March 1989
The International Development Research Centre is a public corporation created by the Parliament of Canada in 1970 to support research designed to adapt science and technology to the needs of developing countries. The Centre’s activity is concentrated in six sectors: agriculture, food and nutrition sciences; health sciences; information sciences; social sciences; earth and engineering sciences; and communications. IDRC is financed solely by the Parliament of Canada; its policies, however, are set by an international Board of Governors. The Centre’s headquarters are in Ottawa, Canada. Regional offices are located in Africa, Asia, Latin America, and the Middle East.

Le Centre de recherches pour le développement international, société publique créée en 1970 par une loi du Parlement canadien, a pour mission d’appuyer des recherches visant à adapter la science et la technologie aux besoins des pays en développement; il concentre son activité dans six secteurs : agriculture, alimentation et nutrition; information; santé; sciences sociales; sciences de la terre et du génie et communications. Le CRDI est financé entièrement par le Parlement canadien, mais c’est un Conseil des gouverneurs international qui en détermine l’orientation et les politiques. Établi à Ottawa (Canada), il a des bureaux régionaux en Afrique, en Asie, en Amérique latine et au Moyen-Orient.

El Centro Internacional de Investigaciones para el Desarrollo es una corporación pública creada en 1970 por el Parlamento de Canadá con el objeto de apoyar la investigación destinada a adaptar la ciencia y la tecnología a las necesidades de los países en desarrollo. Su actividad se concentra en seis sectores: ciencias agrícolas, alimentos y nutrición; ciencias de la salud; ciencias de la información; ciencias sociales; ciencias de la tierra e ingeniería; y comunicaciones. El Centro es financiado exclusivamente por el Parlamento de Canadá; sin embargo, sus políticas son trazadas por un Consejo de Gobernadores de carácter internacional. La sede del Centro está en Ottawa, Canadá, y sus oficinas regionales en América Latina, África, Asia y el Medio Oriente.

This series includes meeting documents, internal reports, and preliminary technical documents that may later form the basis of a formal publication. A Manuscript Report is given a small distribution to a highly specialized audience.

La présente série est réservée aux documents issus de colloques, aux rapports internes et aux documents techniques susceptibles d’être publiés plus tard dans une série de publications plus soignées. D’un tirage restreint, le rapport manuscrit est destiné à un public très spécialisé.

Esta serie incluye ponencias de reuniones, informes internos y documentos técnicos que pueden posteriormente conformar la base de una publicación formal. El informe recibe distribución limitada entre una audiencia altamente especializada.

Acknowledgements

The Office of the President, Republic of Kenya, accepted my application for permission to conduct research in Kenya and issued me with Research Permit No. OP/13/001/10C 254/15, dated 8/7/1982, and the Permanent Secretary for Education, Science and Technology, the Nairobi Provincial Education Officer and the Kiambu District Education Officer allowed me to collect data from the schools. I am grateful for the opportunity.

The research, which served as basis for this report, was generously funded by the International Development Research Centre (IDRC), Ottawa, under grant No. 3-P-82-0074, and I thank IDRC and its officers in the Social Sciences Division for their support. The research was conducted when I was a lecturer at Kenyatta University College and various officers played a role in administering the funds and generally supporting the project.

I have also benefitted a great deal from the generosity of The Nakaima Estate Ltd., and Office Aid Ltd. both of Kampala, Uganda, during the preparation of this report.

In carrying out this study, I enjoyed the professional support and encouragement of many people, and it is a pleasure to be able to thank them. 'Charity', 'Dalia', 'Lloyd' and 'Lydia' the four teachers who were the focus of this study willingly revealed their knowledge and perceptions and gave a great deal of their time to the research. I know that the methods of research quite often constrained their freedom and made them feel 'constantly watched'; but I hope that they will find this reconstruction of some use in their continuing pursuits of professional growth.

Dr. Steve Langdon initially assisted me to visualize much more concretely the scope of the work involved. Throughout the research, and the work leading to the production of this report, Dr Sheldon Shaeffer provided constant and unfailing intellectual and technical support. Sheldon Shaeffer and Dr John Nkinyangi read the original
drafts of this report and gave constructive criticisms for which I am
greatly indebted. Professors Judith Green, Frederick Erickson and
Hugh Mehan provided advice and literature. I have also benefitted
from the interest of and interaction with many other senior colleagues
at the Institute for Research on Teaching, Michigan State University,
Ann Arbour, Michigan; the Ontario Institute for Studies in Education,
Toronto, Ontario, and the Laboratory for Comparative Human
Cognition, University of California, San Diego all of whom shared
similar purposes in research.

While acknowledging the generous intellectual assistance I have
received during the conduct of the research, and in the preparation of
this report, particularly, from Drs Sheldon Shaeffer and John
Nkinyangi, I wish to point out that I am solely responsible for the
views expressed, any errors, omissions, biases and conclusions.

CN
Preface

Teacher inservice education and professional growth are activities undertaken to improve the quality of the teaching-learning process in classrooms and schools. But, all too frequently these activities are organized and conducted for teachers by experts or authorities who believe they know what is good for all teachers and schools and therefore, what teachers and schools should be doing. It is in accordance with such beliefs that new syllabuses, teacher guides and 'joint provincial' work programmes for various subjects are designed so that the teacher might have concrete directives to guide practice which is aimed toward change. But how useful do teachers really find these directives? And what factors guide the teacher in interpreting such directives? What is there in these directives and in the environments of various schools that might make change very difficult to accomplish? And, what kind of help do teachers really need in order to understand change and the demands it makes upon their work in and out of the classroom?

This report which is an account of the processes by which teachers come to achieve full participation in research and in discussion with other practitioners, addresses these and many other questions by revealing teacher perceptions and reflections concerning centrally derived curriculums and the decision that ultimately assemble, guide and characterize classroom processes. Furthermore, the heart of the report is the description of the reflective processes through which more meaningful professional growth and development of teachers may be brought about. Such processes are small scale, intensive, reiterative, time-consuming and practitioner centred as compared with lectures used in traditional inservice educational courses which are large scale, superficial, one-shot, economical and authority or expert centred. This report also presents data on the processes of implementing change in instructional strategies in various classrooms and schools.
The report should be of interest to teachers, educators, curriculum developers and more particularly, to agents for educational change as the data underscore the need to consider a whole series of factors before introducing ideas on change.

CN
INTRODUCTION

The research study, Teacher Participation in Research for Professional Growth, was part of a larger project on Teaching and Learning Biology in Kenya which had the following two aims:

1. To identify practices which take place in schools and classrooms, and to contribute to an understanding of the nature of teacher perceptions and approaches to learning by students which result from these practices.

2. To understand the implications of teacher and student perceptions for school achievement and acquisition of general positive behavioural modalities.

The overall research was guided by a theoretical framework derived from interpretive research methodology (Erickson 1973, 1980, 1986), with interest centred on exposing and clarifying the everyday human meanings in the life of schools. Emphasis was placed on understanding the immediate and local meanings of actions in education as defined by the points of view of school heads, teachers, and pupils. Teaching-learning, whether at school in classrooms or during weekend seminars, was regarded as an event with complex but interrelated processes and products, constructed by the various participants in the event. Processes and results of teaching-learning in particular instances and contexts, were seen as reflecting the phenomena and dynamics of education in wider society. Therefore, the processes, products and contexts of schooling in the arena of particular instances had to be understood if, classroom teachers, teacher trainers and policy makers were to be able to implement realistic intervention in schools, whether for the purpose of improving teaching and learning or for expanding facilities. In examining education as an interpretive process, it was assumed that a holistic perception of education in Kenya should address at least five key questions, namely:

1. What is education as viewed by school heads, teachers, pupils and the broader society in the context of Kenya?
2. What are some of the characteristics of personnel and resources in Kenyan schools?
3. How do various school and non-school personnel actualize the purpose of schooling relative to their definition of education?
4. Where and how does education take place?
5. How should education happen?

In the research study Teacher Participation in Research for Professional Growth, only relatively narrow aspects of each of the above questions were directly addressed. Teachers as key personnel in schools were regarded as not merely sources of research data, but as knowledgeable practitioners who, when engaged in serious dialogue and reflection, are capable of creating new concepts of their work in order to guide their practice. Consequently, this aspect of the research involved discussion, interviews and reflection among four teachers with the general goal of getting them to clarify perceptions of their work. The decision to involve teachers in participatory research was based in part, on the researcher's experiences as a teacher educator, and as a participant in curriculum development and inservice education for teachers. A brief discussion of these issues is presented in the first chapter in order to underscore the significance of teacher professional growth to educational change and improvement.

By involving teachers in the strategies of collaborative ethnography within the wider framework of interpretive methods, it was assumed that effective teacher professional growth is the result of intrinsic professional motivation to improve, and that this intrinsic motivation rests primarily, on the individual teacher and secondarily, on the curriculum. It was envisaged that intrinsic motivation to grow would be much more easily nurtured if a teacher was aware of what he actually did during teaching and how his teaching interacted with students. To work toward such a goal, a strategy based on identifying discrepancies between a teacher's standards of expectation and his actual practice, through discussion in seminars, was adopted. Seminars were designed to serve three purposes. First, they would provide a learning forum for new and workable practices. Second, they would
increase motivation, nurturing experiences and public support from colleagues in order to identify teacher strengths, areas of maximum effect and elements of discrepancy between expectations and actual practice. Third, seminars would be a reference point in talking about and assessing the usefulness of implemented instructional change.

Teacher collaboration in research was undertaken at four levels. First, teachers were involved in aspects of planning for, and collecting data from students in their classes, rating the quality of their own lessons, and attending pre-active and post-active teaching interviews and other more general interviews. Second, teachers participated in seminars where they participated in reflective discussions of two main issues: the factors within their school environment which might affect their work; and, teaching practices as observed from video and audio recordings of their lessons. Third, teachers identified areas within their practice which they felt they needed to improve and using both their own ideas as well as suggestions from their colleagues, implemented instructional techniques designed to ameliorate selected teaching strategies. Fourth, teachers shared their experiences about participation in the research with a larger audience of Kenyan teachers with the aim of encouraging other practitioners to develop channels of dialogue among themselves that might lead to a wider debate on improving the quality of practice.

Data Collection and Interpretation

In collecting data, the five questions eliciting a holistic perception of education in society were viewed within a phenomenological framework. Emphasis and interest were placed not on frequency of teacher assertions of the frequency of events and phenomena related to the issues under discussion, but on types of meanings, the degree of importance of these meanings, and the degree of reciprocity and congruence of perspectives among personnel involved in situations and contexts of interest to teachers. Data concerning the following factors and issues were collected through participant observation, interviews, video recordings of seminars and from short open-ended questionnaires completed by teachers during each seminar:
1. The processes by which teachers come to achieve full participation in seminars as individuals and as a group of teachers from different schools.

2. The manner in which teachers learn to reflect upon their own practices through discussions and interviews and through general involvement in research.

3. The content of the actual discussions, which would reveal the teacher perceptions and concerns about the nature of their work in the classroom and the school in general, as well as the teacher perceptions of their involvement in the research and their reasons for undertaking various activities.

4. The points of view and suggestions generated by teachers and their reactions to various suggestions for change.

5. The processes of implementing change in instructional strategies in various classrooms and schools, the relationships between the types of implemented change, the nature of the implementation process and the resulting total environment in specific schools.

In selecting, analyzing and interpreting data, a conscious effort was made to emphasize the multiple meanings attached to the same issue by different participants. Similarly, there has been a deliberate effort made to provide as much background information as possible, for many of the activities so as to identify the rationale for undertaking certain decisions whenever they had to be taken. The various personal, organizational and situational constraints to the collaborative efforts have also been described so that in suggesting ideas on the viability of the strategies that were employed in this project for future teacher professional growth activities, such factors can be more adequately considered than was attempted in this research.

In reporting the evolution of this collaborative work, there has been less concern with identifying and documenting fast, dramatic, and ostensibly comprehensive positive change that are so often assiduously expected and sought from this type of a project, by
funding organizations and policy makers. Unlike many donor-supported innovations for change, this work was not stage managed or inoculated against the myriad daily pressures (Court and Kinyanjui 1985) to which all teachers, at all levels of schooling work in Kenya are subject. For instance, the teachers in this project continued to carry out their heavy teaching loads and to fulfill their normal responsibilities in school just like their colleagues. One teacher was transferred out of the project schools during the life of the project so that a new teacher had to be 'inducted' into the research. Similarly, the researcher continued to teach full time, and the added administrative burdens of the project only served to materially reduce any 'free time' which would have been for research. It can be concluded with certainty therefore, that whatever achievements, problems, constraints and failures were encountered, they were all genuine features likely to be encountered in naturally evolved projects of this nature.

The report is a reflective description of both the processes of involving teachers in the research as well as the products of that involvement. As such, data and descriptions are identified by teacher names and by first person pronoun for the researcher. The achievements, problems encountered and attempts to resolve them, constraints, and failures as they evolved through the collaborative venture are the central focus. The lessons from this collaborative effort are, in themselves, a powerful antidote to purge policymakers, innovators and agents for educational change, free of the illusion, that positive and durable change will come to the classroom without heavy sacrifices and commitment of time, funds, effort and genuine intellectual thought. Deep, intensive and consistent thinking about the quality of current practices is needed before new practices can be made increasingly effective through small, incremental and localized change.
The report begins with a chapter on some of the factors which influenced the development of meaningful teacher participation in the seminars and in research in general. Chapters 2 and 3 deal with the content of seminar discussion. Chapter 4 discusses strategies and problems of implementing instructional changes in classrooms. In the last chapter, the implications of the results of teacher participation in research to the wider issues of education, research and teacher training and upgrading are discussed.
Chapter 1

EVOLUTION OF MEANINGFUL TEACHER PARTICIPATION IN RESEARCH

Perceptions of Teacher Classroom Practice

Few other aspects of the Kenya education system receives more attention from the public than the link between the quality of teachers and student achievement on public examinations. It is frequently stated in public meetings and newspapers that a 'good' teacher should control student discipline, conduct effective teaching and lead his students to high academic achievement. This idealized image of a teacher as "a smart, knowledgeable and inspired intellectual...a critical educational authority...with a sense of professionalism...and empathy for his students" (Lightfoot 1983) is however, rarely accorded to classroom teachers. Instead, teachers are often described in stereotype portraits that suggest that they are lazy, ignorant, resistant to change, pedantic and lacking in substance and resourcefulness. As a result, speakers and authors in public forums advise teachers on how to accomplish the job of teaching properly.

There is no doubt as to the frequency and abundance of advice given to teachers and schools by Ministry of Education (MOE) planners, policy implementors, university teachers, curriculum developers, officials of the national examination board and the ubiquitous "general public". Equally evident from the same foraums are sentiments that suggest that many schools and teachers have not heeded the advice, and are, if anything, regressing rather than progressing toward positive change. It seems therefore, that schools and teachers may be bombarded, day in day out, with advice and criticism, yet they are unimpressed. Why? How do teacher perceive this advice for change?

During the planning of this research project, the possible causes of neglect by teachers of professional and 'public opinion and advice' on teaching and general educational change was explored at two levels, namely by reviewing the history of curriculum change and teacher inservice education; and, by surveying the perceived credibility of proponents of change by practitioners.
New Curriculums and Teacher Inservice Education

During a conference on Teacher Education in Eastern Africa in 1971, Mazrui (1971) had observed that every educational reform proposed in Africa for the past 20 years had increased the demands made upon teachers in terms of time, effort, commitment and intellectual development. Mazrui described how innovations and changes in the total educational system, such as: vocationalization of the curriculums; decentralization of the syllabuses; shift away from national examinations at every class level of schooling to continuous assessment; and the integration of production and education -- had all demanded more time and work from teachers whose workload was already excessive in a general situation of meagre incentives. At the end of the discussion Mazrui had posed a crucial question: Can teachers prove equal to the task?

During the 1970s, many countries in Africa had developed new science and mathematics curriculums at all levels of learning. The new curriculums were predicated by the discovery approach to learning, as opposed to older curriculums using more didactic approaches to teaching. The discovery approach attempts to combine an emphasis on experimentation, hands-on experiences, student talk about their observations, and their explanations for experimental situations, with teacher use of explanatory strategies that should help students change their experientially based ways of thinking about natural phenomena to more scientifically appropriate ways of understanding phenomena. The didactic approach however, is characterized by verbal and/or textbook instruction as main sources of facts and information about science with emphasis on giving and getting the right answers (Webb 1980). Consequently, programs of teacher inservice education were established in order to update teacher skills.

While in many countries secondary schools had been given an option either to begin the new curriculums or to continue teaching the traditional programmes, the total education system was permeated by an air of uncertainty among teachers as to the usefulness of the proposed changes. By 1977, many of the new curriculums had been abandoned, others had been greatly modified and a number had never actually taken off the ground.
Without the benefit of consistent monitoring of the design and implementation of these curriculums, and without systematic evaluation of the impact of such curriculums in schools, teachers, learners and policymakers were generally unclear about why many of these projects had been abandoned, and whether or not the projects had been useful in any respect. Piecemeal attempts to evaluate aspects of these curriculums appeared to have generated two unequivocal observations. While the use of the discovery approach had been demonstrated during inservice teacher education courses, teachers did not seem to have transferred the new knowledge to their classroom. The teaching-learning approaches of inquiry, independent student discovery and self-direction did not seem to have become actual everyday practices of learners. Why?

At the specific level of new curriculum implementation, it appeared that the proponents of the discovery approach and the developers of new curriculums had overlooked at least, three fundamental factors. First, given the long syllabuses, meagre instructional resources and aids, large class sizes, and the nature and influence of public examinations, verbal instruction and didactic approaches were likely to continue to be extremely important strategies in giving facts and demonstrating skills in spite of new curriculums, purporting to be based on superior cognitive approaches. Second, the curriculum developers and those conducting teacher inservice education courses had assumed that the classroom teacher saw the need to change his approach to the teaching-learning process. As a result, courses had been presented with little reference to needed change in teacher attitudes and perceptions. Third, the policymakers seemed to have similarly, assumed that mandating and legislating change would result in actual change in classrooms, and thus did little to monitor the implementation of new curriculaums so as to be able to discover teacher interactions with it.

At a more general level of inservice teacher education, there is doubt regarding the effectiveness of top-down inserviceing strategies. Traditionally, teacher inservice education has been much more concretely linked to the implementation of new curriculums than with attempts to diagnose difficulties in ongoing teaching practices for the purpose of helping teachers become more effective with existing curriculums. As a result, teachers have often seen inservice education as a process whereby they are told by some authority what they should do in their classrooms. While there may be room for this type of inservice education, it does not
provide or increase a teacher's capacity for autonomous professional self-development. Professional growth is more likely to be nurtured through systematic self-study and the study of the work of other teachers through the testing of ideas by classroom research procedure (Stenhouse 1975). Moreover, the traditional inservice strategy (where for instance, particular biological concepts, such as ecology, are selected for re-analysis and re-structuring in search of an "easier" way to present the concept to learners) is not only laborious and inefficient, but also such a purely empirical attack on the problem of professional growth, that it affords the teacher little opportunity to work towards building a general theory of professional growth that can affect a greater variety of his overall tasks as a teacher (Shayer et al. 1981). Although Teaching and Learning Biology in Kenya was not a curriculum project, it did recognize that in order to bring about improvement in the teaching-learning process, it was crucial for teachers to become convinced of the need for change.

Credibility of Proponents of Classroom Change

In surveying the perceived credibility of proponents of change by teaching practitioners, the following two questions were put informally to 42 teachers in 6 schools:

1. What do you think of the advice and criticism levelled on schools which is heard on radio and read about in newspapers?

2. Do you think schools and teachers make an effort to improve after they have been either advised or criticised?

In asking these questions, each teachers was shown a folder containing 15 newspaper clippings illustrating some of the advice and criticisms given by various MOE officials and writers to newspaper editors (see samples in Appendix A). To attract the teacher's attention to the contents in the clippings, three types of information had been underlined in the text of each, namely:

1. The name, rank and institutional affiliation of the author or speaker.
2. The specific advice given and the aspect of schooling the advice was expected to affect, and the positive aspect its implementation was expected to achieve in schools in particular and in education in general.

3. The specific criticism levelled, the personnel named as culprits and the behaviours they were said to indulge in and which constituted bad practices.

To the first question concerning the validity of the criticism or advice given to schools and teachers, the majority of teachers (34) gave a short curt answer, "nonsense". On the issue of the credibility of the speaker or author, many teachers would request to look at the clippings more closely before retorting, "Who is saying that? Ah- that one! He doesn't know what he is saying". On the question of whether or not schools and teachers make an effort to change, the most frequent reply was, "change? these people should leave us alone. They should do their jobs first and then come and tell us how to do ours and change".

Only one teacher, a school head, gave a slightly different response. To the question on validity of advice he stated:

"Obviously something has gone wrong with our schools. But I doubt whether we have to start with the schools and end there. I think the problem is really our fault- all of us as a nation."

To the question of whether or not schools make an effort to change when advised or criticized, he stated:

"If every time I was criticized by the newspaper, or even by the boys and teachers here I changed, we would never have a single consistent directive in this school. We find it hard enough to get all the students to do what they know is expected of them all the time. Imagine what problems we would have running a school if the students did not know what is expected of them. These students or teachers who do not do what they know is expected of them are just waiting because they think the rules are going to change - today - tomorrow - everyday. The newspapers only give courage to those who just sit and wait"
Teachers often debated the merits and demerits of the arguments, advice and criticism in the newspaper clippings leading the discussion eventually to the usefulness of research. Teachers evolved three main reasons why advice on instructional strategies often emphasized by university staff and MOE officials was regarded as relatively lacking in credibility in school situations. First, teachers pointed out that many university staff did not have teaching experience at the high school or primary school level, so that they did not possess the necessary and tangible experience to form a good foundation for advice and criticism on teaching practices at those levels.

Second, teachers claimed that some university teachers and MOE officials who formerly taught at primary and secondary schools, did not have a long and sustained experience of working in schools. They argued that such personnel were people, "Who got an early chance to run away from teaching and join other institutions". As for those who might have had a reasonably long teaching experience, teachers argued that they did not consider such service as exemplary or distinguished.

Third, since many teachers had serious doubts as to the procedures of selection of and the quality of successful candidates for entry to postgraduate work at university (teachers stated that some people enter into higher degree courses 'very easily') and to policy making positions in the various MOE departments, teachers also doubted the suitability of such personnel as advisors to classroom teachers.

In general, teachers regarded professional teacher educators as not only 'outside' the teaching profession but also as possessing little credible and legitimate knowledge of schools and classrooms as derived from the daily sweat, frustration and toil of classroom teaching. Three factors seemed crucial to teachers in their evaluation of the credibility of advisors, dispensers of criticism and change agents, namely: possession of legitimate and authentic teaching experience for a sustained period of time at the relevant level of schooling; teaching experience of a cross section of schooling levels; and rising legitimately through the ranks of the academic ladder, the teaching profession and at policy making levels. These three factors would seem to indicate that in order to understand teacher perspectives of their work, and to work towards improving
practice, teachers have to work with people they consider believable professional colleagues.

**Definition Of 'Good' and 'Bad' Practice**

The preceding brief discussion of 'public advise and criticism' and teacher perceptions of their credibility, reveal a one-dimensional assigning of meanings to phenomena that is so characteristic of personal perspectives. On one hand, the 'public', in issuing advice and criticism to teachers, rarely considers that teachers may often be caught in an impossibly unresponsive and uncaring situation, where they feel victimized by 'the system'. In such situations, teachers might define the 'goodness' of their practice not just in the narrow sense of good student test scores, but also in a broader concept of successful teacher survival in uncompromising school environments. On the other hand, teachers, in dismissing the validity of most of the advice and criticism, hardly recognize the fact that professional educators, non-educationalists and the public, besides having a rightful high stake in education as citizens, might have an authoritative command of the phenomena of teaching that inspires their persistent interest and commitment to improvement. Two examples, the first from teacher training and the second from research, illustrate some of the actions and attitudes which build and maintain such one-dimensional perspectives.

**Practices at Pre-service Training**

During undergraduate student practice teaching supervised in 1981, a tutor was asked to supervise two pre-service trainees in biology on the same day in two high schools. The first lesson held at 8.15 a.m. was at City High, a 'good' suburban school. The second lesson held at 2.00 p.m., was at South High, a 'poor' rural school 45 kilometres from the first school. When the tutor arrived at City at 8.05 a.m., a guard, at the entrance, directed him through the school complex to the pre-service trainee laboratory. A laboratory technician was assisting the trainee to put the last of the required materials on student benches. At each of 15 locations, there already were a rack with 6 test tubes and three petri dishes; the first containing a white powder, the second groundnuts, and the third, egg albumin. Each location, with a sink and a water tap, also had a bunsen
burner under a tripod stand and three dispensing bottles with Millions Reagent, Benedicts Solution, and distilled water, respectively.

Students, all boys, arrived promptly at 8.10 a.m and quickly settled at the 15 locations by two's or three's. The trainee handed each student an instruction sheet on food tests, and briefly explained the procedures – using the sheet and demonstrating with a set of apparatus from the teacher's desk. After the 'OK, start', all students were on their feet doing the experiments. At 8.20 and 8.30 a.m. a second and third tutor arrived respectively, to supervise the same trainee. At the end of the 80 minute lesson, the three supervisors completed their lesson evaluation forms, talked to the trainee and discussed politely each supervisor's point of view on the lesson. One tutor had awarded the trainee 9/10 "because everything was excellent", a second tutor had awarded 7/10 "because some students who had finished their work early had wasted too much time being idle"; the third tutor had awarded 5/10 "because the teacher had done almost nothing, almost no teaching, since there was a detailed instruction sheet, and it was the students doing all the work".

At 1.45 p.m. the tutor arrived at the small town near South High. It had rained in the morning and it was impossible for cars to negotiate the downward 'path' leading to the school. The tutor pulled into the roadside and walked down the school path. Approaching the school, he saw a car belonging to another tutor which was being pushed out of a ditch by about 10 boy students. The bell for the beginning of class had rung three minutes earlier. The teacher trainee led the tutors to the 'laboratory' - a 60 feet by 20 feet rectangular cement box with a corrugated iron triangle as roof. Three small unlighted bulbs were suspended from each of three uneven beams spanning across the ceiling. It was dim inside the laboratory but some light came through the window and the rest filtered through the numerous holes in the iron roof, caused by the removal of too heavy gauge nails that had probably been taken out because they had originally been hammered into an empty space without a wooden beam underneath to hold them. There were six tables of unequal height that served as student work benches. In one corner stood a large gas canister with four bunsen burners on a table connected to it. The floor was a soggy and muddy pool of dirty water. There were 15 students seated with hands folded to their chest in total silence.
The trainee gave the tutors a copy of his lesson plan. The students were to observe mono- and di-cotyleadonous leaves. The available five hand-lenses were distributed one to each bench. At 2.15 p.m. three students walked in followed by another group of three at 2.30 p.m. From then up to almost the end of the 80 minute period, other students trickled into the lesson until all 42 were assembled. The trainee took 30 minutes to go over the instructions and when he finally asked students if they had any questions there was no response. When he asked whether all students had understood the instructions there was still no response. The trainee asked the students to start their work. As students collected the 4 specimen of leaves from the front bench, the trainee moved around the room urging students to start and to “hurry up to do something”. The sound of the terminal bell was a relief to everyone.

Outside the laboratory, the two tutors got hold of the trainee, and demanded to know why he had allowed students to trickle into his classroom. They complained that: the laboratory was dirty; student uniforms untidy; and students not fully involved in the task of the lesson. The tutors threatened to return the next day to supervise the trainee and that they expected improvement. During a subsequent discussion, one of the tutors, who had awarded 4/10, stated, “that was no lesson. The teacher did all the talking.” He was suprised to discover that his colleague had awarded 7/10 and asserted, “you must have been sleeping throughout the lesson. Nothing happened in that lesson that would deserve even a 2.”

An equally dramatic illustration of the one-dimensional perspective was observed to be at the centre of a controversy between a tutor and a trainee after the former observed a geography lesson. During the lesson, a student had posed a question to the trainee, but instead of giving an answer, the trainee had put the question to another student. The second student had not only been unable to answer correctly but was also unable to restate the original question. The trainee then told both students to look up the correct answer which they were expected to explain during the next subject lesson.

The tutor argued that he did not regard “throwing a student’s question back to the class” a good strategy, ever, adding that it was unprofessional for a teacher not to answer a student’s question within the duration of a particular lesson. The trainee’s “defence” was that while he agreed
generally with the tutor's arguments, he thought the context in his class was important. The trainee had pointed out that the question asked by the student had already been exhaustively dealt with, but because the student was often inattentive, he had missed the explanation. The trainee had added that he had given the question to the second student because he too had been inattentive, explaining that his requirement for the two students to look up the answer and then give an account of it during the next lesson, would encourage students to be more attentive in class. The tutor's uncompromising stance was reflected by his refusal to change his original grading of 5/10.

These examples suggest that 'rating' of classroom observations from the tutor's perspective often ignored the possible influence of the overall context of a school on the conduct of particular lessons. For lessons at City High and South High, five tutors, using the same standardized rating method, but relying on different perceptions, gave varied interpretations of the same lessons. More significantly, tutors were rarely able to listen to each other, let alone, to the trainee's interpretation of the events and the contexts of lessons. Many tutors simply refused to take into account the trainee's interpretation in rating the lesson or in suggesting strategies for improvement. For instance, during discussion at City High, a tutor had pointed out that he had noticed some confusion among a group of students as they started to do the experiment. The tutor had wanted to know why the trainee had not ensured that every student had understood the instructions before letting the students continue on their own. The trainee had explained that since all the boys in the class were bright, he had decided to encourage them to get started by trying to understand some parts of the procedures on their own and work out emerging problems by talking among themselves. The tutor had called the trainee's explanation "an excuse". Similarly, at South High, the trainee when asked why he did not encourage students to ask questions, had explained that, "in this school few students ask questions". But tutors had insisted that the trainee was simply not trying hard enough.

Class Observation Research

During 1980/1981, a short term study of the structure of teacher communication was carried out in 15 classrooms in secondary school biology in Kenya (Namuddu 1981). Part of the data was collected through a
questionnaire designed to discover the relationship between teacher perceptions of their lesson organization and planning and the actual interactive practices they engaged in. Overall, teacher theoretical perceptions of the organization and planning of their lessons were found to be extremely incongruent with what they were actually observed to do during lessons.

For instance, while all teachers had a specific topic for the day's lesson, none had specific objectives for the lesson besides "teaching the pupils on the topic of...". All teachers had said that they had stated their objectives to the class although none had actually said more than the expression "we are going to talk about...". All teachers had indicated that they had stated their objectives at the beginning of the lesson - because they "believed that pupils ought to know what the teacher is going to teach". None of the teachers had suggested that the students ought to know what they were going to learn. Teachers identified no specific skills they expected the students to obtain from particular lessons except "to learn the main points". All teachers had stated that the main factors influencing their lesson preparation were what had been taught before and the level of student knowledge. All teachers said that they always sought to point out to students some relationship between particular lessons and lessons that they had taught before. Yet in only one of the 15 lessons was this relationship mentioned in the course of the lesson.

Teachers pointed out that they invariably planned their lessons basing the sequence on the nature of the topic using a stepwise treatment of the content according to its increasing conceptual complexity and demand. They were unable to state other sequences which they could have used and indicated that their classroom discourse rarely varied from their pre-interactive lesson preparations. One of the most interesting aspects of the teacher responses concerned their rating of student participation and what teachers did in following up student questions and answers. No teacher rated the amount of student participation as being less than 40% of total lesson discourse and many rated student participation as high as 80-90%. Teachers had no specific comments on what had transpired after student answers to teacher questions - apart from the expression that many students had answered questions correctly.
When teacher overall responses were compared to two other forms of data—a theoretical questionnaire on 'good/bad' teaching strategies, and transcripts of actual classroom observations, the following two conclusions were reached:

1. Teachers 'knew' the theoretical expectations of good instructional practices but their classroom practices did not reflect the use of this knowledge.

2. Teacher perceptions of what actually took place in their lessons was out of touch with the observed reality.

The observations from pre-service and inservice teacher education as well as from classroom observation research suggested two hypotheses:

1. Theoretical expositions of pre-service teacher training courses might be out of touch with the classroom situation.

2. Teacher theoretical concepts might not be out of touch with the reality of what actually happens in the classroom, but teacher definitions of the components, quantity and quality of this reality was simply at variance with observer definitions and interpretations.

The first hypothesis suggested that while there might be a 'core' of good teaching practices and strategies that pre-service teacher training can impart, unmitigated prescription and expected usefulness of these strategies in all types of contexts and situations of classrooms and schools was limited by lack of understanding of the contexts in which the so-called 'bad practices and strategies' transpire.

The second hypothesis suggested that while the 'good practices and strategies' might be good and useful in all classroom contexts, teachers might not be sufficiently motivated to implement and use such practices for improvement for at least, two reasons: First, as earlier observed, teachers may find themselves in school and classroom situations where more time and energy is spent inventing strategies to subjectively impose coherence to a given situation than to objectively re-enacting college prescribed 'modes of procedure'. Second, as pointed out during the discussion on teacher regard for 'public advice and criticism', while 'good practices and strategies' may be good and useful in all classroom contexts,
teachers are not sufficiently impressed by the proponents of such 'good practices' to regard the strategies as workable in the classroom.

**Deriving a Research Participation Strategy**

The factors surveyed in the foregoing discussion, namely: effectiveness of traditional models of teacher inservice education; concepts of classroom practice by teachers; credibility of proponents of classroom change among practitioners; definitions of 'good' and 'bad' teaching practices; and the building and maintaining of one-dimensional perspectives on teacher practices, determined the research participation strategies and procedures adopted in the research at four main levels. The first level is the choice of a guiding framework for interaction between teachers and the researcher; the second, choice of schools from which participating teachers would come; the third, the management of seminars; and the fourth, the collection of classroom data to be used during seminars.

**Teachers as Participants in Research**

Until quite recently, the teacher role in research had deteriorated into a passive one of merely giving permission to be studied (Conlin 1980). Secondary school teachers in Kenya were no exception. However, over the past decade, teachers particularly those in schools within easy access to the major urban centres, have frequently participated in research. In addition to often being the subjects of research, many teachers have acted as major sources of data on all aspects of school organization, administration and the nature of pupils. However, due to the types of research conducted, and the nature of the teacher work schedules, teachers rarely get an opportunity to be part of a sustained research effort that has as its primary goal, not simply the involvement of teachers in data collection alone, but also in the understanding of the teacher perceptions of this involvement and its effect on the teacher practices. This project, for several reasons, used the strategies of collaborative educational ethnography between the researcher and four teachers directly affected by the rest of the research project, as a means of both generating research data and instructional change strategies (Erickson 1977; Florio and Walsh 1980). First, it was important to consider teacher inputs as essential in clarifying and checking the validity of observers interpretations of instructional goals and actions (Wallat and Green 1980; Green and Wallat 1979). Second, it was
felt that teachers also need to extend their own knowledge base as well as assume new roles as extended professionals (Hoyle 1975; Stenhouse 1975). Therefore, the four teachers were engaged in long term participatory research processes so that they could reflect upon their perceptions and practices, derive motivation for professional growth, and effect methods and strategies for improving teaching and learning in their classrooms.

Furthermore, awareness among teachers to perceive change as important and necessary was to be built around a system of identifying problems and possible strategies for change, by teachers themselves, through reflection on the mechanisms of research and the nature of their teaching. Using ethnographic methodologies assumed that teaching is context specific (Cook-Gumperz and Gumperz 1976; Erickson and Shultz 1977) which in turn, implied that teacher effectiveness was also context specific. The research format consisting of discussion in seminars was expected to provide the right climate for free expression among teachers so as to reach what Frere (1981) has described as critical consciousness. It was felt that teachers were unlikely to implement longterm and lasting instructional improvement in their work without prior and in-depth consideration of and reflection on the personal and social factors that affect individual practice and its effectiveness.

Selection of Participating School

Because of various organizational constraints, it had been decided from the project’s inception to have a small number of schools and teachers, six and nine respectively in the total project on Teaching and Learning Biology in Kenya. Only four of the six schools and four out of nine teachers were selected to participate in the teacher development seminars. In selecting the four schools, it was recognized that there was in Kenya a vague definition of and a clamour for 'good schools' as determined by the quality of student performance on public examinations. The schools selected therefore, reflected differing levels of educational excellence in Kenya. The four schools, given the pseudo names of: National High, Provincial High, District High and Urbana High, were selected from a range of locations in Nairobi and Kiambu Districts. National High and Provincial High were old, government maintained and high achieving schools with an intake of students from all parts of the country. District High which had average performance, was a relatively new, government assisted school
and selected its students from the surrounding farming and small entrepreneur community. Urbana High which had poor performance, was an old school of relatively recent African management, government maintained with an intake of students, the majority of whose parents either owned small businesses, or worked in factories and in the lower rungs of the civil service ladder.

Selection of Teacher Participants

At the time of negotiating entry into the schools for the entire project, it was expected that perhaps only interested teachers would participate in the staff development seminars. However, the initial decision rested on the school head. It is quite possible that in one of the schools the teachers who eventually took part in the project did so at the request of the head, but other factors came into play. At National High, the head of school directed that inquiries be made with Lydia, the head of department, who expressed interest in joining the project. Although Lydia discussed the matter with other biology teachers, none of the remaining four was enthusiastic after it became obvious that sacrifices in terms of teacher time during weekends, would have to be made for three years.

At Provincial High, the school head also directed that Hugh, the head of department, be consulted. Hugh immediately appointed himself to participate in the project. As head of department, he said, he had no reason to refer the matter to the rest of the staff, even though he would inform them about the project. At District High, the school head selected Dalia to join the project, stating that she was the best and most experienced biology teacher in the school. When it was suggested that there would be no problem if a less experienced teacher participated in the project since the aim was improvement, the head first asked for the names of the other schools in the project and then explained: "we do not want a teacher who might let the school down in a research project involving schools like those". The head said that Dalia was not only a good teacher but that she was also committed to her work and that of the school.

At Urbana High, five attempts to meet with the head of school to discuss the issue had been unsuccessful. However, on three of these visits discussions had been held with Charity, the head of department of biology, who indicated that she wanted to participate in the project. On two of
these visits, discussions had also been held with the deputy head of school who agreed with Charity on her participation in the project but advised her to seek final approval from the head of school.

**Tackling Image Building**

Two factors had been consistently brought up by teachers during the pilot phase discussions of methods used in the total project, namely, the images of researchers held among teachers, and the perceived usefulness of research to school processes and practices.

First, at a meeting to discuss school work at District High during the pilot phase, a teacher had stated;

"Discussing with teachers and understanding what happens in schools and classrooms is useful if you want to write a thesis to get a degree. But to the rest of us it is useless, since most people who work in schools already know what happens in schools. And those who don't work in schools have in reality little interest in what happens in schools as long as the students pass the examinations".

This statement summarized the major points of contention regarding the usefulness of research to the classroom teacher; the image of researchers; the 'real' use of research data and results; the relationship between knowing and using that knowledge; and the nature of interests of outsiders in school matters and by implication, the problems which have to be faced in bringing about change in schools. The frequent but casual exposure of teachers to the conduct of educational research in their schools had conjured up two popular images of researchers, namely: image builders and collectors. The first image, less often quoted than the second, depicted the researcher's role as that of collecting information about the school with the ultimate aim of creating evidence in order to display a good or bad image of the school in the eyes of the public. The second impression of collector, more often implied by veiled politeness, was clearly disapproving and perhaps, more damaging in the long term. This image depicted the researcher as a collector and a busy-body who wasted school time, teacher time and student time, gathering data merely to store it away in a thesis or some obscure document. The researcher was perceived as basically selfish (aiming to get a higher degree for his own
promotion), with little understanding of schools, and with interest in the most trivial aspects of school life.

Second, teachers were highly doubtful of the capability of individual teachers and researchers in specific institutions, to precipitate real change in schools. Teachers frequently pointed out that since teaching at secondary school was conducted by many specialist teachers, improvement in overall school achievement was unlikely to come about by strategies involving only a few teachers (Namuddu 1984).

Since it was unlikely that the four teachers who were to participate in the teacher development seminars would be immune to such contentions, it was important to tackle image building by working out ways and procedures during the seminars, which would address these perceptions. It was realized however, that changing such images, contentions and beliefs had to be a long term purpose of the teacher development seminars and not something that would be disposed of in the first or second seminar.

**The First Teacher Meetings**

Lydia, Hugh (replaced by Lloyd during the second seminar), Dalia and Charity took part in the first meeting held at Provincial High. The purpose of the meeting was to acquaint teachers with one another and for the researcher to explain the nature and purpose of the research project in general, and the teacher development seminars in particular. The first and second meetings were uneventful. Even though teachers had several questions about their involvement in the research, these questions concerned mainly the structural and functional aspects of research procedures and not the conceptual issues concerning teacher development. Teachers had not had an opportunity to try out the activities they were expected to undertake and thus no serious points of debate or disagreements had yet arisen. At the end of the second meeting, teachers agreed to launch the research in each of the four schools. In this process, each teacher was expected to undertake the following activities in his school:

1. Be available for lesson planning interviews and discussion after lessons taught in the research class; prepare lesson plans for all biology lessons taught, but particularly for the research class; and have copies of the lesson plans on file so that they could
be inspected whenever the need arose.

2. Keep a record of biological concepts that the teacher thought were difficult to explain or which he thought students had grasped poorly.

3. Keep a journal of school events, such as new administrative directives, official visitors to the school, and all activities undertaken in the biology research class which were different from normal daily teaching (tests, field trips, punishments etc.).

In addition, general procedure for the conduct of subsequent seminars was agreed on, consisting of four main activities:

1. Teachers would complete a form that solicited information on the three research activities undertaken in the school. The purpose of the information would be to generate material and issues for future seminar discussions as well as to gauge the stability of teacher activities and their perception of their student abilities over time.

2. Teachers would conduct a sharing a session. Here teachers would give brief talks on educational issues of importance in either specific school situations or in a wider context of the educational system. After each presentation, there would be a brainstorming session to compare the rationales for related practices in different schools.

3. Teachers would view a segment of a video taped lesson taken in one of the classrooms of the four teachers. Teachers would be expected to identify either effective or problematic teaching episodes and discuss them exhaustively.

4. Teachers would evaluate the different parts and methods of both the seminar and the research activities in which teachers had conducted. Teachers would also indicate which ideas and suggestions from the seminars they thought they might wish to pursue further or to implement in their teaching and when they would be likely to start such implementation.

The First 'Real' Teacher Development Seminar

When teachers arrived for the first 'real' teacher development seminar at Kenyatta University in November 1982, their first activity was to record
all the research activities they had conducted in their schools during the previous three weeks. None had notes to refer to. Charity and Lloyd completed the forms quite quickly, while Dalia slowly pondered over hers, as she jotted down points. Lydia was able to answer only one of the questions regarding whether or not she had given a test during the three week period.

At the previous meeting, Dalia had been appointed to lead the first sharing session on the general topic of punishment in school. This got off to a very good start with Dalia describing the kinds of punishment instituted at District High, the student misbehaviours attached to each punishment, how often punishments were generally enforced, the opinions of students about these punishments and Dalia's own feelings about giving any of these punishments. Soon a debate arose as to whether or not student punishments were also punishments to teachers since they had to supervise the execution of such punishment. Charity and Lloyd regarded school punishments as merely correctives for the unacceptable behaviour of students while Dalia and Lydia regarded student punishment as infringing on the 'free time' of teachers and teaching strategies. This debate lasted two hours. Meanwhile, I was looking at the clock, worried that teachers might never get to what I regarded, at this stage, as the most important activity, namely, viewing a video tape and identifying effective and non-effective teaching episodes.

After the lunch break, I was able to get teachers to view a video tape of Lloyd's lesson. At first there was a great deal of excitement as teachers saw a class in action. There were numerous questions to Lloyd about the class, uniforms, the laboratory, notebooks, making notes and several other questions, all of which I regarded as peripheral to my central purpose of identifying effective and non-effective episodes. By the time questions subsided, Lloyd was sitting at the edge of his chair, chin in hand and absorbed in his lesson. The other teachers were now checking the clock, throwing furtive glances at both Lloyd and the three other video tapes containing recordings of their own lessons. At this point, the meeting was perhaps, mercifully interrupted by afternoon tea.

During tea break, Dalia commented to Lloyd, "when we go back, we are also going to see ourselves. You have had enough". On returning to the seminar room, I took the cue from Dalia's comment and 'showed' the other three
lessons. changing to a different lesson whenever teacher questions regarding a particular lesson began to subside.

In evaluating the research in general, and the seminar in particular, teachers wrote vaguely about the sharing session, praising Dalia for her "wonderful" presentation. Teachers made positive comments about the food, the video lessons but said nothing about the kinds of activities they wished to undertake in future seminars. I then described the nature of the research activities that teachers had to undertake before the end of the term, and at this point, Lydia asked me how I had evaluated teacher performance during classroom observations, and during the pre-active and post-active interviews and from the seminar that day.

I had pondered with a certain measure of ambivalence over the possibility of such a question since it concerned a difficult issue at the beginning of a longterm project. On one hand, I was aware that if I told teachers my truthful observations, some of which were not very cheerful, they might be tempted to 'stage' data for subsequent observations. On the other hand, if I simply praised or overrated their performance at this early stage of the project, there might be little prospect for change in the future. More significantly, I would not be practicing honesty in generating and talking about research data, something which I was demanding of teachers. Consequently, in answering Lydia's question, I took a critical look at what had so far happened in the research project in general, and during the seminar in particular, and described what it had all meant to me. Teachers were "shocked at the little things" I had observed and which they had not thought about as important or meaningful in their work. Teachers attempted to "defend" themselves by reference to theory, practice, experience, the nature of schools, the rules and directives in schools, personal preferences and several other factors. At the end of the seminar, teachers left in a rather deflated mood.

'Repairing' the Participation Strategy

In retrospect, I realized that the first two meetings had been very deceptive. They had given the impression that the goals of explaining the nature and purpose of the project; of making each teacher aware of the benefits to him of participating in the project; and identifying each teacher obligations to the project; had been accomplished. Reflecting on
teachers' "defence" propounded during the third meeting, it was evident
that teachers were concerned about six factors which the first two
meetings had failed to address properly, and which were now the focus in
the re-evaluation by teachers of their participation in the project. The
six factors were:

1. The researcher's 'real but unstated purposes for soliciting
data from teachers.

2. Rationales and strategies for sharing the time burden among all
participants, including the researcher.

3. Timing of collection of research data in individual classrooms.

4. Credibility of all participating schools for purposes of advising
on instructional improvement.

5. Processes and procedures of arriving at consensus.

6. Techniques for participation in various seminar activities,
particularly video tape viewing, analysis and evaluation.

The 'Real' Purpose of Why

During teachers' defence, it was repeatedly pointed out that I had merely
stated that I wanted to understand what teachers do during teaching,
without disclosing what I really wanted to find out about their work. By
this statement, teachers implied that the objective of understanding what
teachers did, could be sufficiently fulfilled through classroom observation
and need not include teacher interviews and seminars. This sentiment was
related to teacher perceptions of the dubious usefulness of research
conducted by 'collectors' and it underscored the importance of resolving
their scepticism about pre-active and post-active lesson interviews
which were concentrating on finding out 'why' teachers did and decided as
they did during teaching. Teachers had interpreted questions about 'why' as
evidence that I was not simply interested in understanding, for
clarification, but was in fact, challenging the quality of their practice.

This scepticism was related to teacher belief that what teachers did
during teaching was so self-evident that they were unaware of the
necessity to explain the rationale behind their actions. It was not
possible at this early stage to resolve teacher scepticism about my real
research objectives in order to convince teachers of the importance of discussing rationales. But I was alerted to the need keep a visible record of teacher discussions, reflections and debates on various school and classroom issues during seminars, so that by progressively reviewing this record, teachers might come to appreciate that most of their debate had revolved around the task of discerning rationales used in different school and classroom situations.

Sharing the Time Burden

A much more serious matter of concern was the amount of time available to teachers in different schools to do research. Teachers taught an average of 28 periods a week and all of them had to teach 32 periods per week, at one time or another, during the life of the project. Each teacher said that he had to prepare lessons for the 28 periods and mark assignments. Each of the teachers had a half day off-duty which was used for personal business. But invariably, teachers prepared lessons and marked assignments during their own time after school. Of the four teachers, three had school duties requiring 'office hours' besides classroom lessons. For example, two were senior masters responsible for academic affairs for the whole school, all were heads of departments, two were coaches of games and two were dormitory masters. One teacher, who later became a deputy head of school, was also head of department, dormitory master, class master, sports coach, student counsellor and taught 22 periods a week. Lloyd had a wife working at least 25 miles away from home so that he had to look after their two young children. Of the three female teachers one had five children, the second, four and the third had two children, all less than 12 years old. The third woman's husband worked some 1150 miles away from home. Teachers had pointed out that they could not find time to carry out the various research activities within their schools.

It was obvious then that these teachers already had enough work both at school, in classrooms and in their own families. Given the fact that seminar discussions had to be preceded by data collection in the schools, it was clear that participation in long term intensive research was an extra burden to teachers. So quite naturally, teachers wanted to know whether the proposed pre-seminar activities were really essential to the
It was therefore, vital to convince teachers of the importance of the different components of the research. Yet, since teachers had not been involved in the planning of the overall research, they could only come to understand and appreciate the necessity of the various components through increasingly more involvement in the research. Three barriers had to be overcome with regard to time sharing: First, teachers had to understand sufficiently those aspects of the research in which they were involved so that they could get a 'calculable' notion of the amount of time that they would need for the research. This notion was not easy to calculate until teachers had undertaken some of the activities in order to gauge their complexity and how much time the activities demanded in different school contexts. Second, teachers had to understand that since time could not be expanded, research time could only be created by carving it, chip by chip, out of existing programs. This was probably the most difficult issue to tackle, since it involved dislodging two deeply ingrained teacher beliefs namely; that there was no dead time in their existing school programmes, and that teachers were already utilizing all available time as efficiently as possible. Third, teachers had to be convinced that all participants including the researcher, were 'giving up free time' in order to work on the project.

Teachers from various schools, had different notions about how others spent their time. For instance, teachers in day schools argued that since they had to supervise student assignment preparation (prep) during the school day, they needed the weekends to cater to personal responsibilities. They pointed out that it would be easier for teachers in boarding schools to participate in the Saturday meetings. Teachers from boarding schools argued that the 'duties' in boarding schools made it almost impossible for them to attend Saturday meetings particularly, since the boarding schools taught on Saturday mornings. They argued that teachers in day schools "had no problems, no duties, and did nothing on Saturdays." We therefore, had to inspect school timetables to see where some time could be carved out of non-class time. Teachers pointed out that it would be relatively easy to keep a record of the lesson plans, lessons, tests and assignments, but that it would be difficult to keep a journal of events, activities and other happenings in classrooms and schools. Indeed, up to the end of the research
none of the teachers had produced a 'written' journal. This meant that the researcher had to make more visits to schools than originally planned in order to hold discussions with teachers and 'create' a journal for each of them.

The seminar meetings retained the Saturday slot after teachers agreed that they would negotiate with their colleagues to act as substitutes for official duties except teaching. I also had to display my teaching schedule. Teachers needed to see that I had to make time for the research. But in the final analysis, teachers only began to willingly give up time after they had participated in the research and had probably begun to see some intellectual and social benefits out of their participation. Therefore, progressively, as the totality of all activities became self-evident to teachers, and as teachers increasingly appreciated the time-consuming activity of co-ordinating communication between us all, they ascertained that their share of work was done and in fact, often planned their availability to fit my schedules. It was never possible to settle the time issue once and for all. But as already stated, the more the teachers came to understand the nature of the project and its goals in its totality, the more they strived to make time available. At a certain level, reached in early 1984, the demand and creation of time became self-perpetuating. However, we all felt that our schedules were often chaotic, depending as they did, on 'left over' time from official and social obligations for each one of us.

Unpredictable Data Collection

During their defence, teachers had made reference to the fact that I had not given them my schedules for conducting lesson observations, interviews, and more particularly, video recording of their lessons. Teachers had observed that "had they been ready for me", I would have had a less critical reaction to their lessons and their participation than I had got. Lydia pointed out that I should have given teachers the forms for evaluating various research and seminar activities a week before, so that "they would know what I was looking for". These complaints were genuine. Even though teacher timetables were constant throughout a school term, my visits were relatively unpredictable.
The video taping of lessons was a particularly irksome issue for teachers. They expected to "see" themselves presenting a good image and model of good teaching. At the start of the project, which was characterized by an intensive classroom observation, teachers frequently asked me when I would begin video recording. After two weeks, I carried out a series of dummy video recordings before actually making any tapes so that teachers were upset to discover later, that they had not been recorded. Teachers observed that I seemed to have the knack to arrive for recording or to observe lessons for which teachers were least prepared. After debating the merits and demerits of 'prior notice', teachers compromised and agreed that for my purposes, unpredictable data collection could not be helped. But the practice continued to be a source of concern throughout the project so that by October 1984 Lloyd was still able to complain that, "I hate it when you come all the time and then all of a sudden you disappear". During the same period, I had observed Charity's lessons consecutively for three weeks, then I missed the first lesson the following week. When Charity saw me in the middle of the fifth week, she exclaimed: "my God - and just as I was thinking I had gotten rid of you from now on. I did not expect to see you until next year".

Advise on Instructional Change

A more important but subtle problem than the three discussed so far-subtle because teachers did not discuss it directly-concerned the credibility of the four participating teachers for purposes of advising each other on instructional improvement. Evidence of the existence of this problem accumulated as the seminars progressed through two and half years of discussion. At the beginning, there were three issues related to the problem. First, Lloyd and Lydia worked in schools of high academic achievement, while Dalia and Charity worked in low achieving schools. Was there any useful instructional information (or any other information for that matter) which Lloyd and Lydia could learn from Dalia and Charity? Second, since students at Provincial and National, where Lloyd and Lydia taught respectively, were already performing very well in biology and other subjects, were there sound reasons, and was it sensible to expect advise about "more effective" instructional strategies to come from teachers in schools with "known" poor levels of student achievement? Third, was it reasonable to expect Charity and Dalia who taught in schools where the initial intellectual calibre of students was presumed to be low,
when compared to that of students at National and Provincial, to teach as effectively as Lloyd and Lydia? Later in the research, a fourth issue arose. On one hand, Lydia and Lloyd insisted that the high levels of achievement in their two schools were supported primarily by teacher commitment to their job and secondarily by the actual styles of management of the schools and intellectual abilities of the students. They therefore, regarded poor achievement at Charity's school as due to improper prioritization of teacher and student activities throughout the school day. On the other hand, Charity regarded poor student achievement in her school as primarily the result of a combination of poor school management and low student initial abilities. Dalia regarded her school's low achievement as due to the school's poor financial and material resources. Given this range of perceptions concerning the influence of various factors on achievement, was it possible for teachers working in very different social, intellectual and financial environments, to give credible instructional advice to each other?

Since teachers from the 'good' schools regarded school management and student abilities as not really crucial, they in effect, covertly rejected advice from teachers in schools where these factors were problematic. The team had therefore, to agree on who should decide on issues of importance for discussion and whether or not teachers should strive to reach consensus on every issue. There were implicit indicators of conflict on these two questions. For instance, teachers were prepared to discuss video tape episodes by reference to what pupils did and not to what teachers did during lessons. Similarly, teachers preferred to discuss school management by reference to what school heads did and not from how the research teachers personally responded to the head's actions and behaviour. Similarly, student achievements would be more amicably tackled if discussion were based on student initial intellectual abilities and not on the contribution of individual teachers to the continued development of these abilities.

To work toward a compromise, a number of factors had to be considered. First, the project goals, as defined by myself, although sufficiently open, imposed a certain restraint on the kinds of topics that could be discussed. Yet teachers working in schools with different levels of academic excellency, were unlikely to select similar issues of importance. To resolve this issue, individual teachers were asked to choose topics of
Interest for discussion. But it was agreed that different teachers would lead different aspects on the same issue. For instance, Charity selected 'communication in school' as a topic of interest. The discussion began with Charity giving a perspective from her school. The other teachers then presented perspectives from their own schools, while I drew out comparisons and pointed to discrepancies between prescribed practices from the school's written rules, the teacher perspectives and my own observations.

Second, there was the issue of honesty. Teachers did not deliberately try to distort information about their schools, but two prevalent trends in reporting information were noted early in the research process. On one hand, Lydia and Lloyd, were fiercely royal and supportive of their school management structures and policies, particularly, in matters of regimentation, discipline and adherence to tradition. As a result, while defending these policies to the last word, teachers would unconsciously ignore events, settings and processes that might, in fact, be contradictory to the prescribed goals of the school. On the other hand, Charity and Dalia, tended to see very little in their school management structures, policies and traditions that they considered useful or proper, and as a result, they would denigrate such policies at length. My task in these discussions was therefore, to be sufficiently alert to spot these areas where we needed to counterbalance these two extreme points of view without, in the process, leaving their proponents with the notion that their knowledge was being challenged.

We therefore, abandoned attempts to work towards consensus on each and every issue of discussion. This was neither easy nor always achieved by teachers especially on matters of discipline. Teachers often apportioned blame to each other and some teachers frequently felt that the ideals and actions practiced in some high achieving schools "could never" work elsewhere. For instance, the more clearly Lydia and Lloyd reconstructed for Charity and Dalia how well and why things worked so well in high achieving schools, the more the former cemented their beliefs that these practices would not work in the low achieving schools.

As to the nature of advice on specific instructional techniques, it was evident that Lydia and Lloyd, initially envisaged little, if anything, about how research might assist them to improve teaching. After all, their
students were already passing very well in biology. These teachers took for granted the fact that research should strive to learn what lay behind the high and sustained achievement of their schools. A potent weapon of attack on this "feeling of superiority" was found in the very nature of scores that students from these schools had obtained in biology and other subjects in the public examination. Teachers often implied that biology was an easy subject to teach and learn. Lydia and Lloyd often stated that their pupils were bright, hard working, serious, disciplined, interested in learning, and ready to go beyond classroom lessons by reading extensively. Why then were not all students getting the maximum scores? At first, teachers had come up with reasons such as: the nature of examinations, the numbers of students, the time available to cover syllabuses and the quality and quantity of resources. By discussing the constraints to achievement brought about by some of these factors, it was possible to slowly arrive at the idea that there might be something in classroom teaching that prevented many bright students from getting distinctions in biology. Something which discussions with other teachers might help a teacher to pinpoint in his own class.

However, the question of school personalities was not resolved fully throughout the project - except at a level where the highest achieving school in the research could offer something to the high and low achieving schools. This was perhaps why, right up to the end of the research, the teacher from the highest achieving school still felt his school was a 'guinea-pig' which other schools tortured by seeking information from it but with nothing to offer in return. This in itself was an interesting development implying a third image to research, and other outsiders who seek information on "how do you do it?" from schools of academic excellence. Lloyd had described Provincial's plight and torture by other schools as follows:

"There is too much noise. There are people writing to ask for example of our mocks [examinations] our games, timetables, the dates and location of our field trips, the plays we do in drama and the types of assignments in this and that subject. Others are writing to visit us, to debate with us. Practically everyone doing some research is here. It is becoming too much and we have to curtail it."

During the two and half years of research at Provincial High, there was a lot of evidence of "noise" that Lloyd was complaining about. Ironically, it
was because the school did so well that others had come to believe that if "they xeroxed" everything Provincial High did, their own schools might begin to perform just as well. All requests, in the final analysis, involved spending extra time and money writing letters, duplicating documents and sometimes rescheduling school timetables to accommodate visitors. Therefore, during the seminar teachers tried to explore how Provincial's "open door" policy contributed to sustaining its academic excellence.

**Viewing of Video Tapes**

There were three problems regarding identifying effective and non-effective instructional techniques from video tapes. First, teachers expected to see how their whole class and not just portions of it, responded to the teacher's total instructional strategy. Yet video tapes presented an incomplete picture of a classroom at any one point. Therefore, teachers were frustrated and disappointed during many review sessions because video tapes did not often show particular incidents which teacher claimed had been significant in determining the course of subsequent strategies. 'Missing' incidents were claimed as particularly important in situations where teachers felt that, had the incidents been captured, they would have exonerated them from their colleagues' "attacks". Second, video tape viewing is tedious unless focussed so as to look for specific episodes. Since all teachers were expected to view each teacher's tape in turn, it was difficult for teachers to pay consistent and sufficient attention during all sessions. For instance, while the owner of the tape might concentrate on viewing his lesson, other teachers might continue to talk to each other, making it impossible for them to identify objective evidence in order to contribute to subsequent discussion. Teachers adopted various strategies to attempt to harness their colleagues' attention. For instance, a teacher whose tape was under review, sensed that her colleagues' attention was waning, and therefore, began explaining and justifying what was being viewed. This of course, made it impossible to hear the tape and indeed to follow the evolving events of the lesson. Third, teachers tended to concentrate on identifying only ineffective episodes in lessons and then carry over this information to subsequently viewed lessons.

To minimize the effect of these factors, I, as a discussant, constantly tried to redirect the discussion to points which were perhaps of more
interest to me than to the teachers. Since I had always been present during the recording of lessons, taken written notes, and previewed the tapes before seminars, I was in a position to steer the discussion toward my main goal, namely understanding the teacher perspectives on what had happened in lessons and why it had happened. Furthermore, I always determined strategic episodes on tapes which I wanted teachers to pay attention to, give explanations and debate various points of view. Therefore, as a procedure, teachers would view any tape they selected. But as soon their attention was observed slipping, I would direct them to the pre-selected tape episodes. While a lot of tape footage was covered in this way, and while it was possible to limit discussion to a few themes and instructional strategies at a time, these were my goals, my selected episodes, so that it was not clear whether they sufficiently served the teacher goals as well. As a strategy for eliciting data, the viewing of my pre-selected strategic episodes tended to result in a segmented picture of lessons. Yet to me this was the most feasible technique to derive information on the multiple and varied functions of apparently similar instructional techniques used by the four teachers.

**Growth and Looking Ahead**

Ultimately, the seminar discussions had to be linked to all other aspects of the Teaching and Learning Biology in Kenya project. While perhaps, this aspect of research provided teachers with a deeper insight into the inter-relationships between his work, that of the pupils in the research and other teachers and of pupils in the project, its effectiveness depended on some constant and exhaustive review of the research record. Fieldnotes had to be reviewed and “filled in”, student ratings of lessons preliminarily analysed, notes on classroom observations summarized and emerging ideas and themes identified for validation. Evaluation of the seminar activities frequently provided an opportunity to review the totality of the research and to project future activities for both seminars and research. The projection of future activity ended up consuming major research management and planning time. Schedules for the completion of tests by students, times for video viewing by both teachers and students, pre-active lesson interviews, and other meetings were all arranged at this time. Because planning of different research activities was done as a team, teachers came to grasp the totality of the research methods, activities and purposes. Teachers were able to understand the nature of
the data being collected from students and its implications so that they could decide whether or not to disclose the results to students and other teachers or restrict results to the researcher.

Consequently, when the influence of teacher seminars on the rest of the research process was assessed, it was noted that all research activities were more successful in the four schools where teachers participated in teacher development seminars than in the two schools not represented in the seminars. This was not due to unfavourable conditions in the latter schools but because the teachers attending seminars created the required time for research activities. Similarly, there was more rapport between teachers attending seminars and myself than with teachers in the other two schools, possibly because of greater interaction during seminars. Interaction between researcher and teachers and understanding by teachers of the various facets of the project ensured that research time was created at a stage where valid comparison could be made between schools on the same test.

As teachers became fully involved in seminar discussions, they also became increasingly more effective in dealing with various research activities. Judged from the seminar discussion record, participation moved from interviews of teachers conducted by me to a state where teachers interviewed each other and demanded adequate explanations regarding claims made by individual teachers on issues such as, classroom procedures and school management. Chapters 2 and 3 describe the content of teacher discussions and reflections. A better understanding of relationships between various research activities led to better appreciation of the need for each teacher to fulfill his responsibilities to the research project. Teachers helped each other to figure out ways of collecting data in schools and how to look for information required of them in their work. Naturally, teachers had a chance to argue, accept or reject schedules for various research activities using as reasons various administrative or management components in their schools. This gave all participants further insight into the structure of rules, discipline, privileges, responsibilities and different power structures in the various schools.

Increasingly, the seminars became a vital and crucial centre of focus for finding out what was generally happening in the total research project. A
consequence of this was that teachers were able to see their instructional problems and needs more clearly than before so as to come up with personalized goals for participation in research. Similarly, teachers identified specific instructional techniques and broader research problems and goals they wished to pursue in the second year of the research. The nature of teacher implemented instructional techniques and research projects and findings are discussed in chapters 4 and 5 respectively.

The Seminar Record

In two and a half years of research 20 one-day teacher seminars were held. The following chart shows the dates of the seminars, the number of participants, and the major topics of discussion. There were five constant participants, namely, the four teachers and myself. However, teachers sometimes invited a visitor, normally a teacher who wished to either conduct observations or participate in the seminar. The penultimate seminar was attended by all teachers who had participated in the project from all six schools. For the last seminar, each of the participating teachers invited colleagues so that this seminar had 32 participants. With regard to schedules, there was an attempt to hold three seminars per school term. However, seminar dates were always selected to fit all other responsibilities of teachers at school and to their families. We did not hold seminars during school holidays and seminars were often held on consecutive Saturdays whenever there was need to extend discussion on a topic of interest.

The pattern and sequence of activities described earlier, were followed for all seminars except seminars 19 and 20 held on 11/05/1985 and 18/05/1985 respectively. This means that the major topics given in the chart are those discussed under the sharing session. As is evident from the chart, more than one topic was often discussed in the sharing session. This was due to the fact that after viewing a video tape, teachers often held another sharing session that went beyond the prepared topic. Space in this report does not allow the description of the content of all sharing sessions as listed above. Only three strategies namely, questioning, interpreting the syllabus and sequencing biology content are discussed.
Chapter 2

SEQUENCING CLASSROOM CONTENT

"Curriculum development in which classroom teachers are not involved, where the developers merely add or subtract a topic or change the phrasing of the goals, is a lot of hot air breathed out too fast and therefore, cools just as quickly". Lloyd - 1984

Introduction

During this research (October 1982-October 1985) each of the four schools was supposed to be using three different syllabuses, namely; School Science Project Biology (SSP), the Integrated Biology Syllabus (1980) and the Two Cycle Syllabus (1981) for teaching biology at various levels of school. Only the Two Cycle Syllabus was said to be in use in all research classrooms in Form 1 to Form 3. However, because project teachers taught biology at all levels of schooling, all teachers said they were planning lessons using 4 different syllabi (the 4th syllabus being that of A level). In nearly all seminars, teachers addressed aspects of issues on sequencing biology content for various levels of students. Indeed, as teachers participated in seminars with increasing openness and confidence, they became more aware of the intricate relationship between interpreting the syllabus, planning lessons, actual classroom teaching, and assessing learning. The seminar record indicates that issues on sequencing content were discussed under six main questions, namely:

1. What exactly is the contribution of a syllabus to classroom teaching?

2. Where and how do teachers derive information for sequencing topics for classroom teaching?

3. How useful is the sequencing of topics given in the syllabus for actual lesson delivery?
4. What is the usefulness of goals and objectives spelt out in the syllabus for classroom teaching?

5. How do teachers decide on the depth and breadth of treating particular topics since these dimensions are only vaguely treated in all syllabi?

6. What is the relationship between syllabus interpretation and teacher curriculum development?

The following description of the highlights of discussions on sequencing content does not fall into a pattern that would answer the six questions consecutively. This is intentional. First, there has been an attempt to preserve some notion of the origin of discussion on the issue. Teachers did not actually plan to have curriculum interpretation and sequencing of content as major topics of discussion during the sharing session in any one seminar. The subject always came about as a side issue during both the sharing session and viewing of taped lessons. Teacher efforts to tackle the issue were summed up by Dalla during a post-interactive interview when she said, "we are always talking around and about the topic but it is never the centre of our discussion..." A great deal of seminar time was spent discussing the issue, which attested to its importance among teacher concerns. Teachers frequently returned to the issue as a point of reference both during each seminar and across several seminars, in order to explain the rationale for instructional decisions. The fact that no teacher ever suggested devoting a full seminar session to the issue, was probably important evidence of teacher concept of a syllabus as an immutable document. The syllabus prescriptions of goals, objectives, topics and sequence seemed to be defined by teachers as ready-made directives, where no major opinions, changes or questions were expected. And yet, as subsequent discussion showed, teachers had many questions and various perceptions of the syllabus and had implemented numerous changes in official syllabi in order to match these perceptions.

It was evident that while different teacher perceptions influenced action, the key determinant of practice in using syllabi was the school's or department's policy on curriculum interpretation and
sequencing of content. In schools which had clear instructional goals, school-wide management structures and policies on interpreting the syllabus dictated and supported departmental practice and minimized individual teacher requirements to search for workable strategies. In situations where school-wide goals and policy for interpreting syllabus and sequencing content were fuzzy, there was a tendency for individual teachers to evolve and install unaccountable practices of the 'what works for me' type. The rest of this chapter documents these various practices.

**Where are Schemes of Work Used?**

Questions concerning the interpretation of the biology syllabus and its utility in daily classroom work can be viewed from three stages related to teacher professional growth. First, pre-service teacher training courses on teaching methodology have been known to spend a disproportionately long time discussing and, in some cases, practicing the designing of schemes of work, planning lessons, and writing behavioural objectives. Second, teacher trainees during practice are expected to write schemes of work and lesson plans so that supervising tutors can assess classroom teaching with reference to these document adequacies as predictors of good practice. In judging the quality of classroom teaching, tutors often complain about trainees either treating a topic "superficially" or "digressing" into a deeper explanation of concepts than that needed at a particular level of teaching. Third, it is somewhat rare to find classroom teachers referring to schemes of work as guidelines for daily teaching.

During negotiation for entry into the research schools, some teachers were heard to casually comment that they did not "follow" the syllabus. During the initial interviews in January 1983, teachers were asked to show a copy of the biology syllabus and the scheme of work that they were using in the research class. At Urbana High, Charity said that she was using the two-cycle syllabus, which she said she had somewhere. It eventually took her three weeks to find a copy. Regarding the scheme of work, Charity had explained, "there is something for the whole school which is kept by one of the
teachers”. At District High, Dalia said that she was using the two-cycle syllabus, but she could not remember where exactly she had filed the copy. She directed me to consult her head of department who said she had a copy of the syllabus and the schemes of work. At National High, Lydia said that she had a copy of both documents on file, but asked when she had last used them, she said, “I looked through the syllabus when they [MOE] first sent it two years ago, but I did not understand its cycles and I decided not to use it.” At Provincial High, when Lloyd was asked for a copy of the syllabus, he climbed on a stool, researched on top of the storage drawers in the laboratory cum preparation room and brought down a dust covered file. He rifled through it and stated while laughing, “this is the Ministry syllabus”. Sitting down, he reached across his desk and pulled out another file, pushed it across to me and announced, “this is our syllabus and scheme of work”.

During numerous pre-active interviews and observations on planning lessons, teachers consulted textbooks, old teaching books and notes, past public examination papers, their colleagues and even myself but not syllabii or the schemes of work. Where then did teachers obtain guidance for planning and teaching biology at different levels of depth of topic and class?

**Classes and Streams**

During the second seminar held on 12/3/83, a description of the characteristics of each of the four schools was given by each teacher. This led to a discussion of responsibilities of teachers, particularly, the work of class teachers in class streams at one form level. We learned that at Urbana, National and Provincial, streaming of students in forms 1 and 2 was done according to the student’s last name. The idea was to have all possible letters of the alphabet represented in each of the class streams. At District, a provincial school, streaming at Form 1 was based on the presence of both a government maintained and a Harambee (community self-help) section in one school. Consequently, the majority of students in streams 1 and 2 belonged to the government maintained section while students in stream 3 belonged to the Harambee section. With
6, 3, and 4 streams of Form 1 class at Urbana, National, District and Provincial respectively, how were the sequencing of content and teaching achieved to enable all students to sit for the same examination?

At Urbana, Charity pointed out, that sequencing content and teaching were a real problem since it was normal to find teachers teaching at all levels. The rationale for 'vertical' allocation of teachers to classes was that:

"It would be too boring, too repetitious for one teacher to teach all streams at one form level. It might, in fact, be very difficult to teach the same content to all streams since a teacher is bound to get confused as to whether or not he had covered a particular piece of information in Form IA or Form IE".

Lydia explained that at National, "it has always been the practice for a teacher to teach at all streams at one form level in biology". Lydia disagreed with Charity that 'horizontal' allocation bred boredom:

"I find the classes so different that it is hard to think of them as the same. In one, the students may be quite different, they behave differently. Recently we have tried to change to what you have (at Urbana), we had discussed the idea when we had a different head of department, but when he was transferred, we forgot the idea. It has not been revived".

At District, Dalia said that there was no definite rule or tradition. A teacher may teach all streams at one form level, teach across form levels or have a mixture of both. What was important was the total number of hours a teacher taught. Giving her own workload as an example, Dalia stated that she was currently teaching 15 hours of English language, which meant that she could only teach 7 hours of biology at Form 1 (3 periods) and Form 3 (4 periods). Lloyd pointed out that at Provincial, assuming there were enough teachers, which teacher taught at what level and how many streams at a single form level, depended on tradition and the decision of the head of department. The usual practice was to have every teacher teach at each form level in forms 1 to 4. At forms 5 and 6, all biology
teachers taught only a certain number of topics. Lloyd explained that, "a teacher must learn to teach at each level and collect sufficient notes and material so that if he is transferred to a school where he is alone, he cannot say - I have never taught form so and so". With regard to the practice of all biology teachers teaching particular topics at forms 5 and 6, Lloyd added, "many teachers have a preference, either of plants or animals, or ecology. Since the syllabus for forms 5 and 6 is very broad, this enables each teacher to select, plan and teach what interests him most". Lloyd was of the view that although this practice often led to a situation where the head of department was left to teach all the "topics that nobody wants", it at least, ensured that teachers taught what they liked and probably knew best. Lloyd also emphasized the fact that this practice enabled students to have a variety of teachers for the same subject which he thought assisted students to develop their own interests for later specialization.

It was clear that the rationales for allocating teaching tasks to teachers were based on differently perceived utilities for the practices. At Urbana, repetition of the same content was regarded as tiresome to teachers and likely to mitigate against coverage of the same content for all students. There appeared to be no recognition of the fact that whether or not 'horizontal' allocation was implemented, differences in delivered content would still exist. At National, teacher repetition of the same content did not appear to be an important factor since a departmental tradition, including high student achievement in biology, had made teachers believe that 'horizontal' allocation was a successful strategy. Lydia's comment that an idea to implement 'vertical' allocation was abandoned after the head of department was transferred was interesting since it was Lydia who had succeeded the head of department. Had Lydia believed that the idea was worth pursuing, she probably would have introduced it. But Lydia stuck to the departmental tradition adding her own philosophy that students in each stream, even at the same class level, were sufficiently different so as to dictate different dynamics of content delivery in each class.
At District, little thought had been given to considering the consequences of streaming students with regard to teacher ability to deliver content. As a school with few elements of a tradition of successful practice, practicalities took precedence in deciding upon policy and action. In this case, the school utilized the fact that all teachers could teach two different subjects and thus allocation of teaching duties need not reflect concern for the intellectual pursuits of teachers and students, as long as the expected workloads of teachers were

At Provincial, departmental policy recognized that in-subject specialization, interests and preferences would influence teacher efficiency and effectiveness as resources for content. At implementation, the policy enabled teachers to pick and teach topics of interest, develop cumulative capabilities as teachers of biology at different levels of schooling, and act as specialized models for the emerging interests among students. At the same time, the policy enabled the department, and indeed the school, to carry out its traditional role as a site for training future heads of subject departments and senior members of staff for other schools.

The Syllabus

A substantial amount of time was devoted to a discussion of the syllabus during the seminar held on 04/06/1983. The most eloquent discussant on the subject was Lloyd who clearly had more experience than any of the other teachers in the area of curriculum development. Lloyd had taken a teaching course in biology abroad and during his practicum, he had noted that the classroom teacher there had greater responsibility for re-structuring the “official curriculum” in his class. Lloyd had also participated in curriculum development at the Kenya Institute of Education as a member of the Biology Subject Panel and as an author of resource materials and teacher guides for general science for adult education courses. Furthermore, as head of the biology department at Provincial, he was responsible for re-organizing the biology syllabus to suit the needs of school teachers and students.
Lloyd reported that he was generally ambivalent about the mechanisms and processes of curriculum development in Kenya because he believed that it was not possible to teach effectively from the official biology syllabus prescribed by the Kenya Institute of Education. As the second most senior biology teacher in a department of six teachers for eight years, he and three colleagues had recently "revised" the official biology syllabus. Lloyd did not know the origin of the tradition in the department of "ignoring" the official syllabus, but from records of dates on previous syllabi on file, Lloyd had determined that the practice was at least some 12 years old. Why did the biology department design its own syllabus? Lloyd had explained that, "the official syllabus is not a teaching syllabus. Someone, probably from the university, has compiled a lot of topics under one cover. He is not very sure what is teachable and what is not teachable. At any rate there it is. A syllabus. (with laughter)." Lloyd and his colleagues had therefore evolved a "teaching syllabus", presumably, one that consisted of only what was teachable. But Lloyd was quick to add that, "none of the topics in the official syllabus are really unteachable. But they are not easily learned in the format and order in which they are presented in the syllabus". Furthermore, it appeared that Provincial had not had less than two biology teachers over the past 15 years, because Lloyd had emphasized that, "interest is the key issue. We have devised some topics according to interest. Some teachers prefer animals, I prefer plants". But did Lloyd's syllabus really differ from the official MOE syllabus?

Teachers had a chance to inspect copies of Lloyd's syllabus during the seminar held on 4/6/1983 and compare it with the four official syllabi for 'O' and 'A' level biology. Teachers had, earlier in the sharing session, discussed management and administrative structures of schools where the role of heads of departments had been described as, "to ensure that the subject syllabus is properly taught and covered at all levels of schooling". At this stage in the research, Lydia, Charity and Lloyd were heads of biology departments.
Teachers inspected the various official syllabuses and compared them to Lloyd's syllabus. Charity's first comment on Lloyd's syllabus was that it was only a scheme of work. Dalia agreed with Charity; but Lloyd insisted that it was a teaching syllabus and not a scheme of work. Lydia, after carefully examining the syllabus commented more to herself than to Lloyd, "this is your syllabus. Oh! And you teach all this?"

Part of the reason for the three teachers' comments was due simply to the size of Lloyd's syllabus. Unlike official syllabuses for 'O' level, the largest of which was eight pages, Lloyd's syllabus was 35 pages long. Dalia's subsequent comment in this regard was especially revealing as to what teachers expect of a document defined as a syllabus: "If you want to give all that much information to teachers as to what to teach, do not call this a syllabus. Simply say: Teachers' Guide or Schemes of Work. No one will believe you if you call this a syllabus." As inspection of Lloyd's syllabus progressed, Charity commented, "first, I see no topic in the official syllabus which you have left out and there is no new topic in your syllabus which is not in the official syllabus".

Lloyd explained that there were three major differences between his syllabus and the official syllabuses, namely:

1. Instead of arranging the topics according to either logical biological sequence or evolutionary basis (the two approaches attempted in the official syllabuses) Lloyd's syllabus was arranged according to the complexity of topics to be taught and learned within and across various forms, basing such sequence from teachers' previous experience in dealing with the various topics.

2. The syllabus did not merely suggest for example, "that experiments on photosynthesis should be undertaken", but it spelled out the actual required experiments for each topic.

3. The actual specimen and materials to be used in the various experiments were listed per topic and sub-topic.

Were there critical advantages to these arrangements that served biology teaching in Lloyd's school better than in other schools where
a similar syllabus did not exist? Lloyd argued that the designers of official curriculums and syllabi base the sequences of topics on learning theories that rarely represent classroom reality as the teacher understands it and is confronted with on a daily basis. Lloyd described such official syllabi as, "descriptive documents of what to teach and not prescriptive models for practical instruction on the topics therein". Lloyd explained that the organization, traditions, the exercise of authority within individual departments as well as the overall rapport among staff in his school were all important factors in determining actual sequencing strategies of biology content. Moreover, since a wealth of accumulated information about previous practices and their rationale was often on record, the head of department could consult such resources when revising or planning new or different strategies.

For example, the structuring of the scheme of work for each term took into account the seasonal availability, within the school's reach, of plant and animal materials such as crotalaria, algae, fish and frogs. While the school had both an animal house and a fish pond, there were seasonal variations in the abundance and quality of specimens from these two sources, which sometimes necessitated "hunting" for specimen further afield. Consequently, the topics revised and agreed on by teachers at the beginning of each term, were designed to make maximum use of available biological materials. Similarly, student participation in long term projects in biology, such as those for ecology, were sequenced in conjunction with other long term projects in other subjects such as geography and agriculture as well as with reference to other major school activities such as drama, field trips, and athletics so as to conserve intellectual energy, time and money. Lloyd believed that division of labour among staff and individual accountability were basic management strategies in his school which were all reflected in the sequencing of topics in the syllabi for several subjects.

With regard to ensuring that all students in different streams actually covered the same content, Lloyd explained that since biology was a compulsory subject for all students at 'O' level, all four streams per class had to cover exactly the same content each
term and this was the purpose of the detailed syllabus that the
department had designed. Every teacher had to use the syllabus in
order to get a clear notion of what topics had to be covered each
term, which experiments had to be done, what specimens were
available and how many tests would be given to students.

In addition to placing emphasis on the disparities between his
syllabus and the official syllabus on all the above points, Lloyd also
strived to get teachers to see the incongruity between the way the
topics in the official syllabus were arranged and the nature of the
learning process and capabilities available to students at different
levels of schooling. Lloyd stated: "these fellows' [students] brains do
not work that way. (laughter from teachers). The way the student
grasps content, its structure and complexity is very different from
the way the topics and contents are structured in the official
syllabus. But such learning processes are well considered in this
[his] syllabus. This syllabus is based on Piaget's ideas."

Teachers then begun a discussion of Piaget's theoretical framework
and its relationship to sequencing curriculums. All emphatically
agreed that classroom teaching had to begin where "the child is." In
order to help teachers to appreciate the meaning of Piaget's ideas, I
guided the teachers through a brief examination of the
psychological concepts that were stated to support all four school
biology syllabi that teachers were using in teaching I emphasized
the following three points:

1. **All syllabi were undergirded by the following four major psychological
   concepts. A learner learns best by doing. A learner should see
   and be able to communicate what he has seen and learned. The
   conceptual demands of content should be matched to the
   learner's intellectual abilities. And, the content should be
   applicable, and where possible, applied to the learner's daily
   life.**

2. **The four concepts, each of which theoretically imposed on the
   instructional technique certain specific obligations and
   responsibilities, should, in turn, require the learner to
demonstrate specific behaviours concordant with each of the
   concepts as derived from the four different psychological
   stances.**
Since all four concepts were incorporated in the same syllabus, there were inherent contradictions with regard to instructional techniques and demonstration of achieved learner behaviours. Teachers explored the meanings of propositions such as: "learning by doing"; "the child should be shown what he is learning and be able to communicate about it in socially useful ways"; "using what is learned in daily life."; and, "matching content's conceptual demand to learner's intellectual ability", as derived from concepts in psychology. Although teachers agreed with Lloyd that it was "good to keep in mind" the various propositions during lesson planning, they said that it was not possible, in an examination oriented system of education, with strictly prescribed syllabi to have relative ends to schooling for individual students. Teachers finally agreed with Dalia that curriculum designers, being unaware of classroom realities, were too idealistic in prescribing both the goals and the content.

But Lloyd's argument was that the difficulties in integrating psychology during the teaching of biology and in being able to apply different learning theories were not unique to the classroom teacher and were in fact, a more serious problem to curriculum developers than to teachers. Lloyd believed that ultimately, curriculum developers and teachers had to ask themselves the following two questions. Was it reasonable to expect a classroom teacher to evolve an instructional strategy that encompasses all differing psychological concepts? And, what would be the character and temperament of a student who was the product of this 'encompassing instructional strategy'?

Teacher discussion of these two questions appeared to support two beliefs. First, that the classroom teacher, at the crucial point of deciding what to teach and how to teach it, "must interpret the curriculum and devise instructional strategies that bear an image of both the structure of content and the processes of human learning which each teacher identifies in a very personal manner". Second, that teachers as practitioners, already knew how "these fellows' brains work", at least, in so far as sequencing concepts within
major biological topics was concerned. But these beliefs left two other questions unanswered. Was every teacher's knowledge about the theory and practice of sequencing concepts already encompassed within a known psychological stance? Could the meanings and implications of sequencing biology content according to the knowledge of individual teachers violate or at least, conflict with basic goals of teaching biology as a discipline?

On these two questions, Lloyd contended that the most important factor in teaching biology was to have students do as much of the practical work as possible. He added, "of course, there are ultimate goals such as: creativity, developing problem solving abilities and so on. But you cannot sequence and teach daily lessons using these ideas as goals or as daily objectives. They are not tangible". Similarly, Lydia believed that if a teacher paid too much attention to curriculum sequences, he was bound to get distracted by the inherent inconsistencies and contradictions in the syllabus and by public pronouncements regarding the purposes of schooling. Lydia's concern was that the classroom teacher has to get on with the task of teaching whatever syllabus is currently in fashion. Lydia pointed out that teachers had these two options. "Either the teacher sits down and tries to understand the basis of the educational practices espoused in the new syllabus and then designs context-specific practical instructional techniques that implement the new educational goals. Or, the teacher ignores the 'new changes' and uses his experience and common sense to go on teaching as best as he can." Teachers debated Lydia's conclusions intensely, in particular, that aspect regarding the "new changes". The consensus appeared to be that many "new syllabi" did not contain any new changes in content. Rather, the new changes often consisted of substituting populist goals and fancy-sounding objectives for the same goals, activities and objectives, which were found in previous syllabi.

Lloyd added a dimension to the definition of "these old new changes" by asserting that the changes were often very difficult to implement because they assumed that students already had a basic core of information, which was not the case. Referring to Transport
In Animals in the two-cycle syllabus, Lloyd explained that the topic was designed to show the concept of unity and diversity of transport systems found at different evolutionary levels of animals. Lloyd stated, "but our kids cannot get that sort of concept. To teach them so at Form 1 is to waste precious time. What they need is to discuss, for instance, amoeba, its structure, digestion, transport, reproduction, sensitivity and so on. Then other animals should be discussed in the same way, up to the most complex example required. At Form 4, some students may arrive at the unitary concept sought after in the syllabus".

Teachers examined in detail the example given by Lloyd by writing the required sub-concepts on the blackboard. They proposed an outline of a curriculum unit based on "evolutionary complexity" and set out four subsuming elements crucial to understanding the unitary concept. First, students should understand that in all animals there are fundamental similarities in the basic structures, mechanisms and processes by which food, gases, waste products and other body fluids and substances are carried and distributed throughout the body. This is the concept of evolutionary unity of structure and function. Second, students should understand that evolutionary differences brought about by both genetic and environmental factors, result in modifications and sometimes elaboration of the basic structures and mechanisms used in transport systems in different animals on the evolutionary ladder. This is the concept of evolutionary specialization. Third, in order for students to appreciate the meaning of evolutionary diversity, they should be exposed to a variety of structures of the transport system at each of the four levels of biological organization, namely:

<table>
<thead>
<tr>
<th>Level</th>
<th>Prototype</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cellular</td>
<td>Unicellular</td>
<td>Amoeba/paramecium</td>
</tr>
<tr>
<td>Tissue</td>
<td>Multicellular</td>
<td>Sponge</td>
</tr>
<tr>
<td>Organ</td>
<td>Multicellular</td>
<td>Part of system e.g. heart, veins</td>
</tr>
<tr>
<td>Organism</td>
<td>Multicellular</td>
<td>Classes of animals e.g. protozoa, insects, birds, mammals</td>
</tr>
</tbody>
</table>
Fourth, through processes of observation and discussion on transport in animals, students should increasingly have come to realize that:

1. The structure of the transport system and its mechanisms are basically the same in all animals depending characteristically on five requirements of animals; oxygen, food, waste removal, distribution of chemicals for responses, and organism self-preservation.

2. All animals are ultimately an aqueous medium.

Teachers argued that "a student cannot reach these two concepts, certainly not at the lower levels of secondary school, because he does not possess the basic pre-requisite knowledge to build such a unitary concept." Teachers said that during teaching, the teacher should put aside the concept of logical "levels of biological organization", and teach by example, ascertaining that students observe and understand the multiple perceptual evidence of each of the eight fundamental characteristics of all organisms, namely:

<table>
<thead>
<tr>
<th>Structure</th>
<th>Processes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Respiratory system</td>
<td>Respiratory</td>
</tr>
<tr>
<td>Digestive system</td>
<td>Nutrition</td>
</tr>
<tr>
<td>Nervous system</td>
<td>Response</td>
</tr>
<tr>
<td>Reproductive system</td>
<td>Reproduction</td>
</tr>
<tr>
<td>Excretory system</td>
<td>Excretion</td>
</tr>
<tr>
<td>Skeletal system</td>
<td>Locomotion</td>
</tr>
<tr>
<td>Life cycle</td>
<td>Growth</td>
</tr>
<tr>
<td>Circulatory system</td>
<td>Internal transport</td>
</tr>
</tbody>
</table>

Teachers emphasized that students should repeatedly examine the life processes of each example of animal discussed. They admitted that they had no empirical data on whether or not students consistently taught using the two different approaches would learn differently and consequently achieve differently. But Lloyd and Lydia claimed that they had been successful in obtaining high student achievement by consistent use of the structural-functional approach. Charity and Dalia said that they used both the structural-
functional and the evolutionary approach depending on the topic under discussion. It should be emphasized that all teachers saw the usefulness of the evolutionary approach as an organizing principle of biological knowledge. But Lydia and Lloyd did not consider the approach a practical model for sequencing content for everyday classroom learning at secondary school. The two teachers’ ideas did not violate biological principles as dictated by the nature of the discipline since biology is defined, not by the few fundamental generalizations, such as evolution by natural selection, that are currently postulated, but by the practice of the methods of inquiry that aim at verifying the validity of such fundamental generalization.

**Teacher Training**

During discussion concerning the syllabus, teachers had frequently referred to the usefulness of formal teacher training courses in this aspect of the teacher’s work. Teachers consistently argued that during their own training, they were introduced to various theories of learning as descriptive rather than as prescriptive models for practice. When they began teaching, they had found that psychological theories did not constitute a recognizable and adaptable model for practical instruction particularly, in the areas of deciding on appropriate depth of content and sequencing various topics. This discussion was of course, interwoven with a consideration of the quality of the minimum psychological knowledge that ought to form the basis for the classroom organizational skills of a teacher, which according to the teachers, had not been clearly defined and had therefore been assumed to vary immensely from teacher to teacher.

Teachers contended that few teachers were as aware or as informed as they might be, to make maximum use of ideas on learning theories in practical classroom situations. Teachers argued that teacher training courses gave trainees only a core of insights on how to sequence and interpret the syllabus, but that a teacher’s real learning took place during teaching and interacting with the content on a daily basis.
Lloyd argued that it was impossible during college lectures, to simultaneously combine the theory on curriculum sequencing with the practical dynamism of the real class, unless the teacher trainee has had teaching experience before formal training. He stated:

"Syllabus sequencing that is not based on concurrent practical acquisition of the basic and real learning of the psychology and the characteristics of form 1s, 2s, or 3s, is a wasteful exercise."

Perhaps even more significant than teacher beliefs that formal college teacher training programs and courses had neither the experience, nor the scope and time necessary for training in "how to teach", was the revelation that in only a few schools, did a newly qualified teacher find support and assistance from senior teachers on issues of curriculum development. Teachers provided a great deal of autobiographical evidence concerning the lack of support and assistance they had to endure when they were "new teachers". But there was divergence of opinion as to why experienced teachers did not co-operate and offer help to newly qualified teachers on matters regarding curriculum interpretation and general instructional practice.

Lloyd believed that both newly qualified and senior teachers were lazy, asserting, "they do not want to be told how to work and are prone to getting upset when told to do the right thing". He thought that newly qualified teachers were often arrogant, especially the university graduates, who tended to look down on experienced teachers with lower qualifications, adding, "they believe they know everything. So the experienced teachers will have nothing to say."

Dalia and Lydia, however, believed that much of the criticism levelled against new teachers was based on unfair ratings and prejudices. Lydia pointed out that there was too much generalization about the quality of teachers. Charity pointed out that even when a new teacher was not rude or arrogant, there were few schools where senior teachers genuinely tried to assist him. She stated:

"In my experience, when you are a new teacher in some schools, they overload you with work and they don't let you
forget for a moment, that you are an inexperienced teacher."

Three factors frequently stated as contributing to the difficulties a new teacher found in interpreting and sequencing biology curriculums, were summarized by Lydia as follows:

1. "A new teacher has just had three years of advanced university biology from a professor who does not like education and therefore, makes no effort to show how biology can be taught in school. Those professors who try to deal with methodology often use illustrative examples which are not taught in schools.

2. There is too much specialization and fragmentation of content in university courses in such units as physiology, parasitology, mammology and plant physiology. This is a barrier when a teacher first starts teaching at school because he has to learn to integrate topics from diverse specializations, which is something that the teacher has not been taught at university.

3. There is the temptation to teach biology concepts at the level at which the new graduate has treated them at university. The evolutionary approach is a good example. And because this sort of stuff may be too difficult for pupils, discipline problems crop up in class and outside, making the new teacher lose confidence among students and teachers alike."

Teacher discussions suggested subtle but important criteria of defining a syllabus. First, the more detailed a document purporting to be a syllabus was, the more it was likely to be considered a scheme of work and not a syllabus. Second, "how much is to be taught" seemed to be evident in the syllabus, to wit, Lydia's comment: "you teach all this? The following conclusions appeared to have been made by teachers.

1. In all schools teachers do not use the official syllabus for daily teaching. The syllabus used for this purpose is either 'publicly' constructed as in the case of Lloyd's school or is privately carried in the teacher's mind as in the case of Lydia, Charity and Dalia.

2. 'Experience is the best teacher' in acquiring knowledge and skill on how to interpret the syllabus, sequence topics and gauge depth. Experienced teachers do not assist new teachers and pre-service training programs do not impart the relevant skills for
curriculum development.

Records as Evidence of Coverage of Syllabus

There was need to understand how teachers, through teaching experience, went about acquiring knowledge and skills for interpreting the syllabus, sequencing content and deciding on the appropriate depth of treatment of content. The most detailed discussion on the issue occurred during two seminars, held on 17/03/1984 and 20/10/1984. Only two strategies emerged which teachers said they used to get guidance on achieving the right depth in the treatment of individual topics, namely, record keeping and assessment of student learning. The ambivalence of staff, in each of the four schools, toward the strategies and the contextual problems that surrounded the use of these strategies formed the gist of discussion.

Once again, Lloyd provided the teachers with a description of “a working model” which purportedly ensured that all students in different streams of a particular form level covered more or less the same material at approximately equal depth. To achieve this, procedures had been instituted in the biology department as follows:

1. At the beginning of each term, the syllabus for a particular form was reviewed by all staff to get some balance of theory and experimental work and other practical activities.

2. For both the mid-term and end-of-term examinations, only one teacher teaching one of the streams set a common examination for all streams per level, and this examination was reviewed by other teachers before a decision was taken on its final format.

3. Each week during the term, every teacher had to enter into the departmental record file – kept in the teacher preparation room in the laboratory – the work he had covered that week, and each teacher had to mark all student practical, experimental and project work.

4. The departmental record file was constantly reviewed by all teachers so that they could see how far ahead or behind they were, in comparison to their colleagues teaching other streams.
at the same class level.

5. Examination papers from all streams for a particular test were always marked by only one of the teachers, on a rotational basis and vertically along class levels. The teacher was expected to write a report about overall student performance and lead a departmental discussion on the results.

Lloyd was quick to admit that these practices worked very well and smoothly in his department mainly because, "we are all friends so that if there is need to discuss something, we treat it at that level. But beyond this, as head of department, if I see a teacher who has gone too fast or too slow, I alert him to the file". Lloyd added, however, that even if all teachers were not friends, the practices would be carried out reasonably well because of what he referred to as support by management.

Charity had listened to Lloyd's description of "a working model" with a lot of scepticism. Finally she had asked, "are there teachers who don't like to complete weekly records or who complete them too scantily to be useful?" Answers to this question focused attention to the the problems of keeping records which existed at Urbana and National.

At Urbana there were six streams per form in years 1, 2, and 3. Since every teacher preferred to teach a maximum of two streams per form level, this meant that many teachers taught a combination of subjects such as biology and geography or biology and mathematics, and thus belonged to two separate departments. Since various departments used different types of record-keeping systems, it had been difficult to get teachers to follow the models of record keeping in departments where teachers taught only a few lessons (normally three - eight periods per week) of their total work load. For example, if a teacher taught 6 periods of biology and 16 of mathematics, unless the type of record-keeping required in biology was similar to that used in mathematics, the teacher might keep no records for biology. Charity pointed out that in her department, there were four teachers in this category:
"Because in most cases a teacher has more periods in one of the subjects than in the second, teachers develop the belief that in the departments where they teach only a few periods, they are teaching for you, the head of department. So they want to be treated with care, after all, they are only helping you out. So when you ask them to give you a record of work, someone may just scribble a few lines of what he has done, just the topics, as they are in the syllabus."

Charity's predicament led to comments regarding the utility of the MOE requirement that each teacher should be able to teach two subjects. Teachers recognized that the requirement was useful and that it perhaps, worked well in many schools. Yet Lloyd, Lydia and Charity with 12, 8 and 5 years of teaching experience, respectively, had so far taught only biology since graduation despite the fact that they had all spent an equal amount of college time training to teach chemistry. Dalia, who was now teaching biology and English language had in fact, been trained to teach biology and geography.

Lydia explained that at National there was a tradition of keeping the "record work book" but that over time, the purpose of such a record had become subverted. Originally, it had been explicitly understood by teachers that the school head's office wanted to have a record for inspection by MOE officials and parents. However, teachers had also wanted to keep a record of what they had taught and had combined the two records. But since the record required by the head's office was normally submitted at the end of each term, many teachers, instead of filing the record weekly, slowly got into the habit of keeping a personal record, from which they would ultimately compile the record for the head, at the end of term. After a few terms, the record work book had become an individual teacher's property and not an informative file for all teachers to use in order to sequence topics and gauge pacing in various streams. Lydia revealed that the department had tried out a different system where the record work book would be completed weekly or fortnightly, but the system never really worked because many teachers often ignored completing the record. Lydia added, "while teachers were required to complete their work record in one master book, we often had no record of who had the book. Sometimes a
teacher might sit on it for two weeks; then everyone wouldn't bother, because they would say, 'I couldn't find the book'.

Lydia had concluded that the record could not be a useful guide for gauging either equal depth of treatment of content or for controlling pacing of content delivery, since in her department, many teachers had 'horizontal' allocation of teaching duties.

Dalia had also explained that at District, all teachers kept a record of the work covered. Teachers were not really expected to show the record to the head of department, but were expected to use it to set common examinations for streams in the same class. Dalia had explained that there was a meeting of all teachers at the beginning of each term to decide on the common topics to be covered by all streams. Dalia added, "since there is no public record to know what each teacher has covered, in setting the same examination for all streams, different teachers are asked to contribute questions on the different topics, which I suppose is not really very good".

Lloyd pointed out that the setting of a common examination by one teacher for streams taught by different teachers was useful because it increased the ability of individual teachers to gauge the depth at which concepts have been taught. As to worries by teachers that a teacher might be unable to cover all set topics, Lloyd pointed out that in his school, it was rare to find a stream in which any one designated topic had not been taught. According to Lloyd, "what you might find by examining student papers, is that all students might have performed poorly on certain questions - indicating either that the question was too difficult, or that it was misunderstood or more often, that some concept required in the answer had not been properly taught by either all teachers or one of the teachers. But since all papers are marked by one teacher, this teacher can quickly tell the major differences between answers of students in different streams and advise teachers about omissions, misconceptions, and misunderstandings".

Charity, Dalia and Lydia pointed out that in their schools, even though the same examination with questions contributed by
different teachers was taken in all streams, each teacher marked only the papers from his stream and decided on whatever remedial work was necessary. Teachers argued that there were no specific disadvantages to this system since each teacher would know the stream he taught better than other teachers, and that if a teacher did not mark examination papers belonging to his stream, it became that much more difficult for him to do relevant remedial work.

**Teachers' Dread of Public Censor of Colleagues**

Underlying many teacher arguments and counter arguments against public accountability of the work of teachers, was the dread by all teachers to censor other teachers, particularly on the 'quality' of teaching. It was precisely this dread to censor teachers that made it impossible to institute and maintain public records of work at National, District, and Urbana thus failing to get teachers to see the work record as as both an intellectual and administrative tool. Moreover, schools often kept a record of work simply to avoid tight situations as described by Dalia, "it is very embarrassing to go and ask students for their notebooks after a teacher has left. The head of department ought to know where and at which topic each teacher has stopped".

Teachers suggested that different reasons had to be argued and understood in each school context, if teachers were going to contribute to keeping a systematic public work record. The implementation of these public record-keeping systems demanded either mutual responsibility or authority. For instance, in Charity's school the head of department could, "tell a teacher who has been rushing, to stop teaching until others catch up with him". And yet there was no help to this "rushing" teacher on what to do with students while they sat idly waiting for other streams to catch up with them. Dalia thought that the practice in Charity's school was unacceptable; and Lydia had asked in exasperation,

"But with what authority do you tell me to stop teaching? It is very difficult to tell a teacher to slow down or hurry up. Her own classroom practices may not allow this. I would never ask a teacher to stop teaching to wait for others to catch up. I might
encourage the teacher to revise or to increase practical work. But you are not going to tell the teacher: 'go into this or that detail'. He will ask you, which detail? And how do you know I haven't gone into such detail already?"

Lloyd pointed out that the "stage of physically" asking teachers to slow down or to catch up with other others should not arise in a situation where teachers have for instance, clearly understood the topics to be covered each term, realized that the end-of-term examination would be set on "topics set to be done during a term" and not "on topics actually done in each stream", and kept a weekly record of their work. Lloyd argued that a combination of these three practices often ensured that teachers remained in touch with each other and synchronized teaching. While admitting to the rigidity inherent in the practices, Lloyd pointed out:

"We have to insist on some level or rules otherwise some problems will arise in some classes. It is important for the teacher to know that if he is too slow he will have to rush at some point and even set up make-up classes. If he is too fast, other teachers are not going to rush to catch up with him and it will be his problem to convince students so that they don't think that he is not teaching them, when he begins to do revision in the middle of the term."

But Lydia insisted that every teacher was an authority in his class and that while other teachers could give advice, no one, including a school head, had authority to tell a teacher to stop teaching, even if the syllabus had been covered. Lydia's statement underscored each teacher's, including teacher trainees, immunity to censor by colleagues, by reference to "how helpless" she had felt when a teacher trainee had "really upset her class."

Lydia and Dalia's research classes had been allocated to teacher trainees for six weeks. In Lydia's case, the teacher trainee had wanted to be assured constantly by experienced teachers in the school that he was teaching concepts at the right depth. Lydia had initially explained to her colleagues that the trainee "has a problem - he keeps referring to you - to find out whether he has done the right thing." After three weeks, Lydia had sought advice from the
seminar because she was becoming worried, since she was not sure if the trainee was actually teaching at all. Asked why she did not sit in the class as an observer, instead of having to speculate on whether the trainee had really taught, Lydia replied, "that will undermine him even more. What I have now decided is to have him write everything that he has taught after each class so that I can, later in the year, go over it with students".

In Dalia's case, the problem was different but equally illustrative of the dread of collegial censor. After the trainee had been teaching for two weeks, it had been "secretely" reported to Dalia that the teacher trainee was not teaching well. He was said to be confused and teaching by reading from a textbook. When Dalia was asked what she intended to do about the problem, she replied that she was not going to do anything to "embarass the poor guy" while he was still in the school. Dalia added, "even his college tutors know his work. He is teaching by reading. You should see the textbook, it is very well used! I will have to re-teach everything when he goes."

Lloyd's research class was, at one point, briefly allocated to a teacher trainee who, in an effort to identify himself with students, pointed out to them that what they were learning was not that important or useful in later life. Asked what he had done in the situation, Lloyd stated, "I told him his role was to identify with teachers and not with learners, otherwise he would soon have discipline problems."

Teachers described other examples of schools where the maintenance of public accountability records of work had been abandoned "because some teachers might use them to undermine others". Thus in some schools, teachers were "allowed" to mark only examination papers from classes they had taught because "if another teacher marks them, they might start undermining you". Similarly, teachers did not like the practice of different teachers teaching different topics to the same class in the same subject. Lloyd had admitted that he was always embarrassed whenever he received complaints from students that a particular teacher was giving them sub-standard content as compared to other teachers. Lloyd stated
that in a situation of this nature it was important not to undermine another teacher, adding, "I always tell these students that teachers are different and that they cannot expect the same thing from all them. And since everything taught is written in some book, I encourage them to read. I also tell them that at university, some professors will read to them notes they made 25 years ago and there is nothing you can do." It did not seem to occur to Lloyd that the last part of his remark could undermine teachers at another level.

Dalia, Charity and Lydia pointed out that it was precisely to avoid the "inevitable comparisons of teachers by students" that they allocated forms rather than topics to individual teachers. When I pointed out to the teachers a subtle contradiction between Dalia's comments about the teacher trainee's "using the textbook" and Lloyd's encouragement of his students to read, all said they could not see any contradiction. Except for Charity, the teachers were very secretive about the source of their notes and the kinds of textbooks that formed their references. As Lloyd had pointed out during a pre-active interview, "if they [students] know where you get the notes, they won't listen any more". The trainee who "used the textbook very well" had been chided because his instructional strategy consisted of reading and using a textbook in front of students, which teachers believed, had suggested to learners that "the teacher did not know what he was teaching".

When I suggested that since teachers generally, hid their reference resources in order to maintain authority over knowledge and to appear to be its primary source, Lloyd's advise to students to read instead of taking the teacher seriously, had undermined this authority, teachers resolved the apparent contradiction easily. Lloyd had stated: "Form 1 to Form 4 students need to have a deep appreciation of the teacher's authority on both content and discipline. At higher levels in forms 5 and 6, even though the same appreciation of a teacher's authority on content would be useful, the students are at a level where they know that a classroom teacher cannot be the final authority on content, and there is no point in a teacher hanging on to this no-existent authority".
The Technician as Interpreter of the Syllabus

Only at National and Provincial were the topics to be covered per term, and sometimes, the sequence of topics, determined by availability of resources. But the experience of the laboratory technicians in the two departments were often used to interpret and implement the curriculum. Lloyd pointed out that, "here one soon learns that if you are a lazy teacher it's you who suffers. Because the laboratory technicians keep another work record, the practicals record book." Lloyd explained that every teacher must indicate in the practicals record, the date and time of the proposed practical, the number of students, and whether students will work in groups and how many groups or as individuals. Teachers must also list the materials, specimen and apparatus needed per student or per group. The technicians always inspected the record daily and then made preparations if the teacher's request presented no problem. If however, a teacher wanted to stage a practical for which specimens were either unavailable or more frequently, insufficient, then the technician would inform the teacher of the realities, and the teacher would re-organize his class procedures.

Expounding on the role of the technician, Lloyd added: "the biology technicians are quite important in influencing a teacher's classroom methodology and the sequencing of topics. They are more than just laboratory technicians. They have trained many teachers in the art of possible practical work. These fellows know what will work and what won't work". Lloyd explained that for many a new teacher textbooks are the most important source of experiments. But sometimes one cannot have all the ingredients needed to stage a particular experiment so that substitutes have to be used. "Our technicians have all these substitutes at their fingertips". A more important role of a good technician as a resource on workable practices, was identified by Lloyd in regard to textbook prescriptions for experimental work:

"Textbooks often write out experiments as if students learned only biology the whole day. Sometimes the textbooks use an experiment that takes 2 hours to work when there is a simpler experiment which might take less time. But as a new teacher
you don't know this. So our technicians use their immense experience to modify experiments by substituting steps and resources to lead to the most economic means to get experimental results. Many times I might not know where things are and how to put them together quickly and efficiently, the technician knows.

Lloyd explained that it was up to individual teachers to get an accurate record of the "new" experimental procedure designed by the technician and give it to the students. Technicians also frequently suggested the number of practicals needed for full treatment of a topic so that this number, rather the number of periods per topic, defined for the teacher aspects of the depth of coverage for particular topics. As a result, hours for teaching biology in forms 3 and 4 at Lloyd's school, were allocated according to the number of compulsory practicals each student needed and the number of topics set for coverage in a term had to fit into practical work timetables. Moreover, technicians know the duration of certain key experiments and often advised the head of department on the timetabling of lessons at particular form levels for example, on days where longterm observations could meaningfully be undertaken by students without interruption by other lessons in the same laboratories.

Lloyd was persistently reminded by teachers that he was "lucky" to have technicians who were trained as well as committed to their work. The technician who worked in Dalia's laboratory had been trained, but as Dalia pointed out, "he is not interested in the academic aspect of the laboratory. He will prepare what you ask him to get, but beyond that, he has not developed the interest in terms of keeping records of anything such as aspects of experimental work." Charity told teachers that at Urbana, the technician was not trained, "he is a young man who tries his best to provide for teachers' needs. But as technician for two laboratories, biology and physics, rather than a subject technician, and without a departmental system to inform him in advance of proposed practicals, he does not make advance preparations, and spends most of his time running between classes and laboratories during actual students' practicals."
Getting a Firm Grip on a Definition of Depth

Despite reliance on strategies such as work record-keeping, examination setting, and sometimes assistance from knowledgeable technicians, teachers had to decide the depth at which to treat a particular topic during classroom discourse because as Lloyd pointed out:

"Regardless of how much discussion you hold with your colleagues before class, you as an individual, you have to stand in front of a class and at the end of it, have yourself and the class feeling that you gave enough content, not too shallow, not too deep, challenging yet sufficient."

How did teachers know when they had reached that balance point, and how did they define it? Lloyd admitted that he still did not have a formula that worked well for all classes after 12 years of teaching. Apparently, the difficulty in evolving a cure-all formula was partly due to the diversity of students within each stream and across different form levels. Lloyd pointed out that this problem was greater at forms 1 and 2, where students were still trying to develop interests and set themselves patterns for learning various subjects. At higher class levels, "the teacher knows that the students have the basic foundation of concepts in the subject. Students also know that they must read around and beyond the lesson in order to get a more in-depth understanding of the new concepts discussed during lessons." Teachers agreed with Lloyd that at higher levels, depth was much easier to handle by simply exposing students to all the concepts that teachers knew were required for public examinations purposes. Lloyd believed that it was not possible to provide sufficient depth on a particular topic for the whole class in such a way that none of the students would feel bored or be left behind. Giving his research class as an example, Lloyd stated that 20-24 students were average achievers, 10 high achievers and 6 low achievers. In teaching such a class, he defined "sufficient depth" by selecting a core of five average achievers and teaching the whole class as if it consisted of only these 5 students. The right depth of content was then determined mainly by the
teacher paying attention to how well the five students performed on the following two criteria:

1. Giving a correct and full definition of the concept as required by biology.

2. Giving a correct and full definition of the concept as required in public examinations, school syllabus, and tests.

In addition, in expounding on the dimensions of particular concepts, Lloyd kept in mind three other factors namely:

1. The number of times students were likely to meet an expanded or a more sophisticated treatment of the same concept throughout the four years of secondary school.

2. Teacher's experience as to whether or not students generally found a particular concept easy or difficult to learn.

3. The depth at which the teacher has previously taught the concept and the main questions that previous students have raised while learning the concept.

Holding simultaneously in mind the two criteria and the three factors, Lloyd said that he would teach a concept focusing basically on the reactions of the five average achievers in class. The easier it was for these students to grasp the concept, the greater would be Lloyd's "feelings" that the concept had been treated at the right level of complexity and depth. However, Lloyd did not totally ignore the rest of the class:

"If I explain something and I start getting confused questions from the average group or the top ten, then I have to backtrack. If I get correct answers from the low achievers, then I know that the top ten and many average achievers have been bored."

Charity told her colleagues that her strategy for gauging depth was different from Lloyd's. Convinced that regardless of what she did, one half of the class, at least, would not grasp much of the content, Charity could not base her definition of depth and her pace on students' reactions. Rather, "I teach from what I know the students should know. I know the right depth. I give explanation and more
important, I give dictated or written notes so that if a student did not understand the classroom teaching, they can read their notes. Dalia stated that she was not consciously bothered by questions of gauging depth or moderating pace, explaining, "I use basically the concept as I know it. I also know the expected depth from what public examinations ask. I don't think students have any learning problems because of these issues. As long as the teacher teaches, they will learn." Lydia said that she had no one cure-all formula, but used many formulas depending on the topic, the students and the level of class. She challenged Lloyd as to whether it was possible for him to use his formula all the time. After a debate as to whether or not Lloyd ever felt himself "pushed" by impending examinations and other factors such as loss of class time because of school outings, Lloyd admitted that he could not always use the formula, explaining, "There are times when I must teach a topic the way I want to teach it. If it turns out to be too easy, that's not a problem. If it turns out to be too difficult for the students, then we work on simplification."

What was evident from the discussion was how experience was so crucial in determining the sequences, the depth and the pace of the curriculum at both school and classroom level. "Experience", "feelings" and "just knowing" were the operational words that signified important guidelines to teachers in their work. Asked how a new teacher without "experience" could cope with these curriculum demands, Lydia replied,

"I think people are unfair to expect too much from a new teacher. A new fellow has to make mistakes. The point is: Does he learn from these mistakes?"

As to how a new teacher would recognize his mistakes and attempt to remedy them when he was the sole judge of himself, Lloyd explained:

"I think this is where professional ethics comes in. To me this means that even in a school where there is a single teacher for each subject, there should be a curriculum committee to look at the results of students in tests in various subjects compared with national expectations which are fairly well represented by past
examinations, and try to see what teachers can do. These
curriculum committees could be drawn up along lines such
as the sciences, the creative arts, the languages, the social
studies and so on. It is difficult to believe that a teacher of
physics is so ignorant as to have no clear notion of form 1
chemistry."
Lydia was quick to advise that a teacher ought to be very careful in
looking at past examinations as indicative of "expected" national
depth in treatment of various topics because: "I hear that often
times these questions are not well set, and that markers construct
new marking schemes - not quite the same as those provided by the
original authors of the questions so that even here, gauging depth is
still an issue to be sorted out”.

Summary and Conclusions

This chapter began with a quotation from Lloyd expressing the
futility of developing new curriculums at the national level, without
involving the classroom teacher. Throughout the discussion, it
became evident that the teacher is the authority in his classroom,
certainly, in the crucial area of curriculum development at the
school and classroom levels. It was interesting that throughout the
discussion, teacher statements gave unexpected support to the kind
of research activity in which they were involved. After all, the
problems of curriculum development at the Curriculum Development
Centre, the school, department, and at individual teacher level; and
of interpreting official syllabi in lesson planning, during lesson
delivery and during assessment of learning are essentially those of
attempting to match content to an informed interpretation of the
psychology of human learning in specific classroom situations. But
since there is not a single psychology of human learning and since
human learning of different types is probably needed for different
purposes, 'real' learning probably takes place under many different
situations. The matching process is therefore, difficult and can fail
or indeed, be faulty at any of the points mentioned above due to at
least three reasons. First, many findings from classroom empirical
psychological research, which purport to test the processes of
human learning behaviour, are inaccessible to many teachers in the
classroom. Second, if and when these findings are accessible, the findings may be incomprehensible because of the paradigms and language used to describe and interpret classroom learning. And third, if the findings are understandable, they rarely, as Lloyd stated, represent reality as the classroom teacher understands it and confronts it on a daily basis. Teacher beliefs about the limited contribution of generalized theories of instruction, curriculum or class management to improvement in teaching were generally similar to assertions by other teachers who have engaged in reflective thought about their work (Lampert 1985). Therefore, teacher participation in reflective discussion of the nature reported in this chapter, probably enables teachers to gain access to empirical experiences from research and from other practitioners.

The utility of official syllabi, written schemes of work and lesson plans, as evidence of work covered in each classroom and the depth at which this work was handled, was shown to be extremely problematic in the teacher discussions. Some professional educators and teacher trainers have argued that since qualified teachers do not make use of schemes of work and lesson plans and yet continue to teach well, education courses should spend less time on teaching the skills of preparing schemes of work and lesson plans. Other teacher trainers and professional educators have countered this argument by stating that teachers do not teach well without written lesson plans and schemes of work but that the reason teachers do not make use of such schemes and plans is because they do not have the skills to prepare these aids. Therefore, education courses should spend more time teaching these skills and teachers should be encouraged or even be forced to develop and use these aids.

As is often the case, both arguments embody correct as well as faulty insights as the preceding discussion has eloquently shown. It would appear that the contribution of the official syllabus to daily teaching, although important, is short lived. Teachers appear to consult the official syllabus, perhaps, once a year to get a 'mental' record of the topics therein, after which the syllabus is shelved. Teachers do not appear to use the syllabus to derive goals and objectives for daily teaching. Schemes of work do not seem to fare
any better, perhaps confirming recent research on teacher planning and decision making which have revealed that teachers typically do not use the objective-based "rational" model stressed in textbooks (Brophy 1980) syllabi, schemes of work and teacher guides, but instead, concentrate on the topics and activities included in textbooks and concrete curriculum materials as they seem to relate to needs of students for examination purposes. Yet it is important to note that in a department where teachers made their own detailed syllabus, teachers were said to consult it frequently, since it provided information not normally found in official syllabi or schemes of work. But as was clear from subsequent discussion, teacher access to and use of a detailed departmental syllabus was supported by a constellation of other practices such as strong departmental leadership, systematic record-keeping, professional assistance from technicians and a school-wide concern for the intellectual interests and professional growth of teachers. This suggests that merely providing syllabi and schemes of work without other supportive services and practices, may not be sufficient to motivate teachers to make use of them.

It was also noted that teachers tended to regard the centrally prescribed syllabus as ambiguous and restrictive, implying that if teachers were left to plan and develop curriculums suitable in their individual classrooms, their teaching might become more effective. Research in the the U.S. where teachers generally have more discretion in classroom curriculum development suggests at least, in elementary mathematics, that even though teachers in theory tend to value such freedom, in practice they are often textbook-bound (Schwille et al. 1979). Elsewhere, Schwille et al. (1986) caution against the tendency to place teacher roles in curriculum decisions at the two extremes of professionals either excercizing independent judgement or following directives, instead of taking a middle position. They argue that viewing the teacher as a policymaker or political broker is one way to reconcile the polar positions: "from this point of view teachers enjoy enough discretion to be influenced by their own concepts of what schooling ought to be. But at the same time, teachers will choose (or be constrained to choose) to follow certain outside pressures. These pressures may be
either consistent or inconsistent with what they want schooling to be" (Schwille et al. 1979). Such research would seem to underscore the need for careful thought in all aspects of curriculum decentralization to the school.

Teachers emphasized the difference between teacher training at college and 'learning teaching on the job'. A difference which should be useful in clarifying what a teacher trainee is expected to do while teaching at school and what he is taught to do during teacher training. At college a teacher trainee is taught how to handle a series of biology concepts that have defined dimensions of content, structure and application. On the job, however, "teaching teaches teachers" concepts that consist of defined dimensions of content but within a wider range of structures and applications in terms of age levels of pupils, intellectual development, conceptual demand, styles of cognition, social interaction settings, school and classroom contexts. A teacher cannot define these dimensions once and for all, since they are always changing. In addition, curriculums change. Since a teacher is often trained only once on how to learn to teach, emphasis in training should not probably and simply be on developing his skills for designing schemes of work and lesson plans, but more significantly, on skills that will enable him to transform knowledge and skills at different times in different contexts, i.e. configure and integrate theory with practice in different school contexts.

For instance, the seminar discussions tried to configure and integrate knowledge about the theory and practice of interpreting curriculum for teaching, but teachers could not resolve the question of 'good sequence and proper depth'. What evolved was some notion of the various practices that teachers in different schools used, employing differing rationales to implement different practices and outcomes. Of course, teachers identified shortcomings in each practice, but they came to learn that it would be futile to attempt to remedy these practices without first considering school-wide rationales that undergirded the existence of the practices. Yet teachers gained deeper insights into their "mental" and practical work.
As an observer in all four schools, I was surprised to find that what had at first appeared as ‘doing nothing’ in some schools, was after all ‘doing something’ and what had at first appeared as ‘doing too much’ in other schools was simplified after I learned why doing less would have amounted to ‘doing nothing’. The foregoing discussion and summary suggests four recommendations for trainers of teachers, curriculum developers and school management.

1. Teacher educators should lay more emphasis on helping teachers to learn to reflect upon their work using theories about learning as starting points. Teachers tend to regard such theories as immutable and perfect and therefore, inapplicable in schools and to students who have known imperfections. Reflection should assist teachers to begin to resolve these and several other conflicts and lead to a healthier outlook toward the inherent contradictions in teaching and how theory can help to guide practice.

2. While there is still a place for a short and concise presentation of a national curriculum in the form of a syllabus document, syllabi meant as teacher working documents should have under one cover what are now called teaching guides and examination regulations for syllabi. It seems that one of the reasons why teachers ignore official syllabi is that they contain scanty guidance for teachers on the crucial issues of interpretation, sequencing and pacing of content.

3. Whenever new curriculums are designed, not only should classroom teachers be involved in the exercise, in order to infuse into the debate a proportionate amount of reality in the selection of content and methodology, but more significantly, be advised whether the new changes in the curriculum are in content, in methodology or both.

4. While national organizations such as teachers’ unions, employers such as the Teacher Service Commission, and MOE inspectorate should all continue to prescribe a ‘code of professional ethics’ for teachers, it is ultimately, the duty of the school head, school management and senior staff in each department to build and maintain strong departmental leadership through which genuine curriculum development, staff accountability for teaching, and teacher professional growth can be supported. Strong and insightful departmental leadership should encourage in-house censor by colleagues, which is so essential to professional growth; systematically guide new teachers; and set up a visible system of teacher and student support for teaching-learning.
Chapter 3

DEFINING FUNCTIONS OF QUESTIONS

"There are times one is not in a mood to answer questions from students, that is, when you want to accomplish something. You have to cover a topic. But in either case, we assume too much..." Dalia (1984).

Introduction

It was perhaps inevitable that teacher attempts to analyse the structure and meanings of classroom events, by viewing video tapes of their lessons, would focus their attention on the issue of defining student participation during the teaching-learning process. In classrooms where the average number of students is 38 to 40, teachers have to make critical decisions in order to involve students so as to actively contribute to the lesson. The most obvious strategies through which teachers can ensure student contribution to the lesson are to pose questions and to solicit questions from students. But teachers appear to have various purposes for either posing questions or soliciting questions from students. The discussion in this chapter presents these various objectives of questions as perceived by the four teachers.

Defining Student Participation

Teachers generally defined student participation in the teaching-learning process at three levels, always keeping in mind, the nature of biology as a practical subject, and the nature of "good learning" as defined by theories of learning that emphasize 'learning by doing'. The first and most frequently stated level of student participation was the degree to which students in class contributed verbally to the structuring of classroom dialogue and events. Two types of events were categorized under this definition, namely, students answering teacher questions, and students asking questions. The
second level was student involvement in practical work such that each student, in fact, did something in carrying out the practicals. This definition was perceived as being most useful at the individual student level. But teachers clearly emphasized that under current school circumstances, with inadequate resources, materials and tools, this is an ideal that is rarely achieved. The third level of student participation was defined in terms of student activities such as making and maintaining a written record of the content they have learned and completion of assignments, including activities such as, class collection of specimens and observation of on-going experiments during student free time.

Functions of Questions

Teachers easily conceptualized student participation in their classrooms by referring to the function of questions. As Charity commented, "questions are so common - that sometimes you don't realize you have posed one". After viewing a number of tape segments which showed questioning episodes, teachers realized that examination of their questioning mechanisms and strategies was in essence an examination of teacher interaction with students. As earlier pointed out in Chapter 1, teachers preferred to tackle issues indirectly wherever their own roles were at stake, teachers therefore concentrated on identifying the different functions of questions which fortunately, lead to defining the social and intellectual contexts surrounding the evolving of questions.

Academic and Social Functions of Questions

Right from the start, teachers stated that questions served two main purposes, academic and social, and that a single question often contained elements of both.

The following question episode during Lydia's revision lesson on Germination illustrated the two purposes.

Kanini: I still don't understand what the endosperm is.
Lydia: You still want me to define the endosperm? After all this? (With a tone of disbelief and a sweeping gesture toward students).

Kanini: Yes.

Lydia explained during the seminar, that Kanini was asking for "another definition and description of the functions of the endosperm". Lydia stated that she had chosen the words in her response carefully, and that the tone and structure of her two questions were meant to tell Kanini, the student, and the class as a whole, that "I disapproved of Kanini's attempt to make the teacher repeat information that she had already dealt with". Yet Kanini's request was not denied, as Lydia repeated the required description of the endosperm.

Another example of a similar situation from Charity's class on the topic Teeth also illustrates the academic and social function of questions.

Charity: Where do you expect to find this formula [dental]?

Faith: In dog.

Charity: No.

Martha: In cat.

Charity: No!

Faith: In cow.

Charity: Noo!! Haven't you people looked in your mouths?

From the teacher analyses and descriptions similar to these two examples, and from constantly asking and reflecting on why they had posed particular questions, teachers were able to come up with three main functions of questions. They are: lesson building, masterly assessors and alertness harnessing, all of which were subsumed by the academic and social functions. Chart 1 summarizes the types of functions that teachers evolved.
Lesson Building Questions

Defining Points of Entry To Lessons

Most of the questions asked by teachers were for the purpose of soliciting information and new concepts from students in order for teachers and students to construct a lesson together. The underlying assumption by teachers was that students, either from their own experience or previous lessons, knew concepts that were relevant to the content of current lessons. The actual content might also be information students might reconstruct from concepts given earlier within the present lesson.

For instance, Lydia's Form 2 lesson transcript covering the first 4.5 minutes of an 80 minute lesson on Food Chains and Food Webs, reveals clearly the purpose of questions as builders of lesson content as well as social controllers.

01. Lydia: Good morning.
02. Class: Good morning Mrs...
03. Lydia: Today you are nice and quiet. (with tone of suprise)
04. Class: (Exchange of knowing glances and nods of heads).
05. Lydia: Did we complete everything about the food chains...?
06. Class: Yes/No. (Lydia pauses and surveys class to imply annoyance at interruption by student chorus)
07. Lydia: ... so that now we can do something about food webs?
08. Class: Yes/No.
09. Lydia: I don't know whether you have all this in your books (Lydia moves from her desk, peruses through Anne's exercise book, returns to her desk). You were not asked to make any food webs?
10. Class: Yes/No.
11. Lydia: You were?
12. Class: We were not.
13. Lydia: I remember, I left you to copy the food chains on the blackboard. Have you completed that?
14. Class: Yes (some giggling at the back of the room)
15. Lydia: OK (long pause to show disapproval of giggling from the back). Now we will continue. Somebody had asked a question. What had somebody asked?
16. Class: (Silence)
17. Lydia: Someone had mentioned something about vultures which we could not say anything about. Before we go on, just a word or two about food chains. Give me an example of a food chain; the longest food chain that you have.
18. Class: A food chain?
19. Lydia: Yes. The longest food chain you have.
20. Lydia: Stella? (does not have hand up)
21. Stella: (Riffling through notebook) Uh. I cannot find the longest.
22. Lydia: Sara? (has hand up)
24. Lydia: That is a long one. Yes.
25. Lydia: What bird is this that is eaten by the hawk?
27. Lydia: You have seen birds eaten by hawk? (with sceptic tone)
29. Lydia: What I wanted to know is whether you have seen birds eaten by a hawk?
30. Class: Yes/No.
31. Lydia: (Interrupting the chorus) No! Just put up your hand and tell us your observation. What have you observed?
32. Mona: I think it does not eat other birds except chicks, because it does not fly very well and therefore, cannot catch other birds.
33. Lydia: I see. That's a good idea. Did you get that? She says she does not think that the hawk eats other birds. The reason it eats chicks is because they have lost the ability to fly. So one could imagine that it might eat other chicks which cannot fly. So we might as well put it here (Lydia writes on food chain on BB) as chick or hen - to be specific, isn't it?

Teachers analyzed the different elements in structuring questions that build lessons. Lesson building did not consist of only compiling academic content, but also building class atmosphere (lines 1–4),
finding points of entry into the lesson (5-17), revision (9-17), and challenging students (17-20). But as can be seen in line 34 Lydia used Mona’s answer in 33 to expand on (and reverse the meaning?) the topic of food chain. In several other episodes such as Lydia’s, teachers pointed out the difficulty of separating academic questions from their social meanings, since context was important. For instance, Lydia explained that her comment that, “today you are nice and quiet” was to be understood as an appreciation of new student behaviour in the context of a class that normally made a lot of noise during transition, but which had been quiet 5 minutes after the bell.

According to Lydia, the first few questions serve both to assess learning procedures as well as to give her a point of entry into the lesson. Teachers held a heated debate regarding whether or not it was ethical for a teacher to depend on student recall of what content had been covered during a previous lesson. Lydia and Dalia felt that the teacher did not ask these types of questions with total ignorance of where to start and how much he or she had covered in a previous lesson in order to determine a point of entry into a new lesson. The teacher had this knowledge. The function of these questions, “was simply a technique to get students involved in the lesson right from the start by remembering what they had covered before”. Lloyd pointed out however, that Lydia’s questions did not show that she intended to mobilize relevant student concepts, adding, “even though you refer to the nature of the coming lesson – Food Webs – your main concern is how much the students had completed in the previous lesson”. Lloyd pointed to what he referred to as an even more disturbing aspect of Lydia’s strategy, namely, the question: Did we complete everything about the food chain? To Lloyd this question suggested that either Lydia had given students a very clear notion of what exactly they were to do on the topic of food chains or that Lydia expected students to be able to know what consisted of “everything”.

Lydia had perused a student’s notebook at the beginning of the lesson, presumably to ascertain what students had done which, as her statement: “I don’t know whether you have all this in your notebook”, would appear to suggest, she did not know. What did Lydia
mean by all this? Lydia explained that during the previous lesson, she had discussed four different types of food chains, drawing them on the board. She had moved very fast through the 40-minute period giving a great deal of information. In fact, she had paused only twice to give students time to write. But at the sound of the bell, the students had not "copied" the food chains into their notebooks, yet they had to move to another lesson. This was why Lydia did not know whether or not students had managed to copy the food chains after the lesson. Even though Dalia found no fault with Lydia's technique, she said that she rarely, if ever, used it in her own class, adding, "I am a bit like Lloyd who keeps a very accurate set of notes of his lessons". Lloyd also pointed out that it was precisely the kind of student response and reaction which prevented him from posing that type of question. The inevitable 'yes/no' response always meant that the teacher had, as a next step, to check a student notebook in order to see who was telling the truth - those saying 'no' or those saying 'yes'. Charity agreed with Lloyd and Dalia, adding that for a teacher in her situation, where most students were lazy and rarely completed their work, if she looked at "the wrong notebook" she might re-teach the same stuff many times.

However, what Lloyd referred to as the strongest argument against Lydia's purpose in asking "checking" questions, was that as a teacher, one wished to project an image of mastery of knowledge, and of being in full control of one's lesson in relationship to what to do, where to start and where to end. Lloyd felt that this was as important an aspect of teaching as giving the substantive content. He felt that teachers should avoid questions that portrayed them as lacking that firm grip on the events in a lesson and that confidence, which is crucially determined by the points of entry into a new lesson.

What the other teachers failed to grasp, and which Lydia herself knew but was unable to articulate to her colleagues, was that her technique fitted in and was in fact, a crucial element to her overall daily instructional strategy. Out of 78 periods during which Lydia was observed teaching, she asked this type of question at the entry into a lesson in 49 periods (62.8%). In 32 (65.3%) of the 49 lessons...
she examined a student notebook as part of the question but in 28 (87.5%) of these 32 instances, she did not begin where she had left off in the previous lesson. Was it possible that Lydia did not really know where she had stopped, or where to begin?

I encouraged teachers to search for a pattern among all lessons that Lydia had started with checking questions. This was a time-consuming exercise as teachers had to zoom up and down taped lessons in order to see the beginning and end of consecutive lessons and also skim through whole lessons to get an idea of the sequence of student activities. We found that the lessons prefaced by checking questions were a mixture of double (80 minutes) and single (40 minutes) periods and theory and practical classes. The only pattern among all lessons seemed to be the nature of the ending of the previous lesson. Using an edited tape showing only the beginnings and ends of lessons we identified 15 taped lessons which formed "previous lessons" to the ones in which checking questions were posed at entry. In all 15 previous lessons, it seemed that students were not writing down anything but were simply listening to Lydia at the time the end-of-class bell rang. At this point the problem was solved for Lydia. She exclaimed, "Oh, I see!"

Lydia was always very strict about receiving complete student attention while she lectured. This meant that if a lesson ended while she was talking, students would not have time to make notes on what she had been saying. While students were taking notes, Lydia would go round, monitoring, marking, reading and suggesting changes and corrections to student notes. It seemed that the monitoring exercise enabled Lydia to get a notion of where students were at particular points in the lesson, so that she would probably make a mental note and decide on where to begin the next lesson. With no 'visible' record of work covered, and without the benefit of this 'final' monitoring, Lydia seemed lost at the beginning of lessons, and had to refresh her memory by asking checking questions and examining student notebooks.
Questions, Knowledge and Authority

It was interesting that even though Lydia failed to explain and argue her point clearly enough to convince her colleagues, she remained convinced that there was nothing faulty in her technique both professionally and academically. This was because, underlying the issue of whether or not to use checking questions, and peruse student notebooks, was each teacher's perception of knowledge and authority. Lloyd for instance, said that he feared to create the wrong impression among students. Charity feared that not only would she waste time re-teaching what she had already covered, but that, by looking at student notebooks and asking questions of entry, she would most probably not get the correct answer to her question. Implicitly, Charity believed that the records of work of her students were prone to inaccuracy. Charity's perception of the ability of many of her students had led her to give up on the idea of "mastery learning". Her statement that "if you look at the wrong book" implied that there was nothing more to be done for a student who had the 'wrong notes'. It would seem that while Lloyd's definition of authority was based on his fear of being a model of ignorance, Charity's definition of authority was predicated on fear of being misinformed by ignorant students. This subtle but important distinction reveals precisely the different ways both Lloyd and Charity perceived the capabilities of their students.

Lloyd saw his students as bright, alert and able to read beyond him. He believed that they followed lessons closely and understood the largest proportion of content. Three of the funniest episodes observed in Lloyd's research class were of three students who, when asked to restate questions that Lloyd had posed, were unable to do so. On all three occasions, Lloyd threatened them with a punishment, namely, "to run around the block 10 times". As these threats were being made by Lloyd, the rest of the class was shouting: "Murram! Cement!", and roaring with laughter. Murram and Cement were the school nicknames for two local foods Njenga and Ugali. Njenga is made from loosely ground maize grains and Ugali, a thick paste, is made from finely ground maize meal. The school's
folklore was that if a student ate too much of either foodstuff, he tended to become stupid and forgetful of his classwork. The purpose of running round the block was to loosen the *Murram* and *Cement* hold over a student's physiological processes especially, mental functioning. Lloyd might have suspected that if he had frequently begun his afternoon lessons by asking questions that suggested that he had forgotten the end point of the previous lesson, his students might have been tempted to shout at him "*Murram! Cement!*".

Lydia, however, did not define her authority in these terms. While she appreciated the fact that a teacher should know her content, she was so convinced of this knowledge herself, that she could not see how it could be questioned by students. Moreover, she had built up an open relationship with the class which was fairly honest. If a student for instance, had not done homework, she would tell Lydia before a new lesson. Lydia's perceptions of the abilities of her students was as positive as Lloyd's. But Lydia expected students to have a good deal of explicit responsibility in keeping track of the whereabouts of lessons. There were several occasions when Lydia would ask her students, "are you sure?" - or she would conclude by stating, "alright, if you say we have done everything, let's go on". Furthermore, answers to many questions asked by students were left open, because as Lydia pointed out: "I didn't want the student to remain with the impression that I gave her that answer". In other words, Lydia wanted students to assume some responsibility for some of the accuracy of the content 'built' in class.

A segment from a lesson on *Food chains and Food Webs*, illustrates Lydia's emphasis on student responsibility for aspects of content built through questions.

01. Mona:  
...some people eat dogs

02. Lydia:  
Where?

03. Muithera:  
In the... (name of the country)

04. Mona:  
And I have read it in a book.

05. Lydia:  
Which book?
A book my parents have.

Was it a novel?

No. I have also read another book and it says the... (name of people) eat dogs.

And you believed it?

Yes.

That people eat dogs?

Yes (class laughs).

Has anybody here seen people who eat dogs? (class laughs and five hands go up including that of Cole).

Cole, you have seen them? (Class laughs.)

I wanted to give another food chain.

No. Let us first make a note in our notebooks noting that in this last food chain, Mona and Muithera say that man eats dogs. (Class roars with laughter.)

In summary, the four teachers had different perceptions as to the function of questions that encouraged students to help the teacher to "find" a point of entry to a lesson. On one hand, Charity, Dalia and Lloyd believed that, in their own circumstances, these questions had no positive function. Lydia, on the other hand, used these questions frequently not only to serve the function of locating the entry point to a new lesson but also to enforce the responsibility of students in keeping track of content delivered during previous lessons. Apparently, a teacher's perception of the intellectual abilities of students may lead to viewing the functions of such questions in different ways.
Questions Leading to Divergent Exposition

A characteristic of lesson building questions which teachers addressed was referred to as divergent exposition. Teachers thought that Lydia's lessons were particularly prone to this feature. Lydia often admitted the difficulty she was facing in attempting to catch up with other teachers. She said she did not appear to progress at all. One reason for this was that Lydia tended to disgress more than any of the other teachers from a topic at hand. The "dog eating episode" that was quoted above, was an example of the type of digression teachers termed divergent exposition, because Lydia was said to have abandoned the main thread of a lesson by asking questions that went beyond normal classroom expectations. But teachers had difficulty in defining and agreeing on what was meant in practical situations, by digression and going beyond normal expectation. In order to understand the causes of digression, teachers examined episodes from each of the teacher's classes in terms of questions initiated by students and involvement of students in "visible" classroom activity.

For example, teachers observed that in Charity's lessons there was on the average very few questions initiated by students so that occasionally, a question might be posed either seeking clarification of something written on the blackboard in abbreviation, or seeking an explanation of a concept. After reviewing one of Lydia's lessons in which there were as many student questions as Lydia's, Charity had lamented, "some of ours will not ask even if they have not understood". Dalia's lessons were also characterized by an almost total absence of questions or even any kind of noise from students. After reviewing Dalia's lesson, Lloyd had commented, "you have no confrontation. Nothing starts at the other end. I would find that a challenge". Dalia had however, replied: "they were quite busy; it's a good class". Dalia's definition of student involvement in her lessons, even though theoretically congruent with that of her colleagues, was different in practice. She tended to regard what she had referred to as the bustle and noise- a constant hum or even bubble, screeching of stools, reaching across benches, unauthorized
talking, constant movement, chorusing, laughter—which was observed in lessons taught by Lydia, Lloyd and Charity as indicative of discipline problems. Lloyd's class normally posed several questions which were often subtly but strictly curtailed from straying from the point under discussion by Lloyd.

In order to understand the causes of digression or lack of it, I encouraged teachers to consider how the different patterns might have developed during the first two terms of year 1 when teachers would normally set and reinforce rules for classroom behaviour. Teachers therefore, concentrated on identifying lesson episodes where teachers would define criteria for activities such as asking and answering questions, leaving the classroom, coming late, and using various resources. Teachers found that right from the first lesson, "hands-up" was required and expected and often demanded of any student who wanted to answer a question, to ask a question or to address either the teacher or the class. But as teachers examined subsequent lessons, they found that all of them tended to enforce this rule differently for individuals or groups of students in their classes.

For instance, Lloyd was able to reconstruct the process by which his class had come to learn not to ask "irrelevant" questions. Apparently, at the beginning of first term, about 14 very bright students occupied the first two benches in the laboratory. Whenever Lloyd demanded hands-up, his purpose was to evaluate how many students knew the correct answer and how many did not. Since Lloyd tended to gauge the complexity of his lesson and questions by concentrating on a core of 5 average students, he rarely solicited answers from the group of 14 bright students and those below average. In the case of the bright students, Lloyd argued that, "it is useful that those students who always know the correct answer do not put up hands all the time". In the case of the latter, Lloyd believed that, "if you are going to ask questions of the slow student, you need time and patience. And if a slow student gets too many questions wrong, I stop asking him because others will learn to make fun of him." Asked how the slow learner was likely to improve and get encouraged, Lloyd commented, "I will ask him only when I
am almost certain he knows the correct answer”. With regard to the very good student, Lloyd stated: “when I am really pressed for time, and I ask a question, then I will ask someone whom I am sure knows the answer. If you are in a hurry, you just want the right answer.” Lloyd stated, however, that under normal class conditions the very good student in his class would keep putting up his hand, adding, “but I won’t pick on him. The best thing is to ignore him. Somehow he comes to understand that you will pick him only as a last resort. He is not discouraged since he knows that he knows the answer and that you know he is good.” On questions initiated by students, Lloyd had stated, “I do not allow certain kinds of questions. I have told my students that a question beginning with, I don’t understand, is evidence of mental laxity. This way they will learn to ask clear questions.”

Lloyd’s resulting instructional strategy was therefore, one that encouraged expendiency in content delivery within a time perspective. This meant that over time, the bright students, who might have been expected to bring a new slant to the understanding of concepts through divergent questions, had been made the silent majority. The average students, who were allowed to be vocal, had severe curbs put on the type of questions they could ask. The low achievers seem to have been relegated to conduct their own battle of acquiring confidence. This is not to say that Lloyd’s brightest pupils did not ask or answer questions. They did. But they never organized themselves in an influential, albeit unofficial, coalition to lead class events.

After Lydia had examined a number of episodes of digression in her taped lessons she admitted that she was aware of the disadvantages of digression. She pointed out that digression came from three sources. First, whenever she asked a lesson building question she often discovered, from student answers, that there was a definite gap in knowledge concerning some subsuming concepts. “I cannot bear to think they don’t know or are not clear about these elementary concepts because if not, they will not understand the subsequent concepts”. Second, Lydia realized that a full understanding of biological concepts in a particular lesson could be
achieved by students only after they were able to recall some simple concepts which they had previously dealt with generally, in other subjects such as chemistry, physics, mathematics and geography. Lydia said that she knew that often, the students had covered such concepts but, "I try to put them in their biological perspective, and get the students to see the relationship to the biological concept at hand." Third, Lydia admitted that there were altogether too many student questions in her class. But she said that she did not want a solution to that "problem because it is not a problem".

In general, Charity, Lloyd and Dalia had problems similar to Lydia's with regard to the first and second causes of digression. The difference was in the instructional techniques the other teachers chose to deal with these problems. Lloyd and Dalia pointed out that they tended to be precise, explain the gaps in student knowledge, either of biology or of other subjects, and get on with the planned lesson. Lydia and Charity said that they tended to use the opposite technique, namely, soliciting such explanation from students through knowledge-building questions. This technique was always more problematic for Lydia than for Charity. On one hand, because Charity believed that she had an accurate perception of the intellectual capabilities of her pupils, she therefore, often arrived at the point of "giving the answer" to students earlier than Lydia. On the other hand, Lydia's underlying assumption was that, "If students tried hard enough, they would get it right". Lydia was prepared to give students as much opportunity as possible to try, even if they digressed. Lydia was quite adamant when she stated, "I cannot move on without ascertaining that the student has got some form of answer, either from me or from the other students".

Questions Leading to Convergent Exposition

Lloyd's lessons were described by Lydia as convergent exposition because Lloyd consistently focused content and questions to only those points, concepts and elements that he thought were important. Lydia believed that this technique was not "very fair" to students who might want to know more than what was allowed by the
teacher. Lloyd’s reply to this concern was that classtime was not
the occasion to debate student opinions on various biological
issues, adding, “once you allow opinions as content, you open
yourself to digression. I would rather converge my teaching to a few
points than be led by student questions into all manner of opinions.”
The following extract from Lloyd’s lesson on Growth Hormones
shows the kind of convergence that Lloyd constantly brought to bear
on the exposition of content and the use of questions.

01. Lloyd: I want you to look at the two diagrams 1 and 2.
(two diagrams representing two shoot tips on the
BB). Why is the shoot in diagram 1 bending?

02. Ndagi: Because the shoot has grown there in that part.

03. Lloyd: Why has it grown? And in which part?

04. Mark: Because it has no hormone.

05. Lloyd: Let me put markers here. (Puts signs at location of
bending and growth.) In 2 you see the shoot
is straight. But as it grows, as we said last time, it
is bending to the left. Why?

06. Ndagi: Because the growth hormone which was
concentrated there has gone away.

07. Lloyd: Now! What you are saying is that the shoot is affected
by the hormone which has moved away - the
concentration is reduced. This is what you want
us to believe?

08. Ndagi: (Silent)

09. Class: Yes.

10. Lloyd: What other possibility could have caused the
growth? In this - let us call this section A, and this
section B. What other possibility could have caused
growth in section B? What other possibility would
have caused it? There is still another possibility.
Yes? (to Luke who has a hand up).

11. Luke: The hormones are running away from...
12. Lloyd: Oh its you! Do you know what you mean by running away? You can run away from me. (Class laughs.) But is it possible that the hormone runs in a plant? You can describe it better.

14. Lloyd: Now, where is this hormone produced?

16. Lloyd: At?

18. Lloyd: At the?

20. Lloyd: Aaa! Yes, by what?

22. Lloyd: No. There is still something wrong. Now listen. I did mention that the plant hormone is produced at the tip of the shoot or root. Let us be clear about that first. OK? Then what happens?

Lloyd said that he had two main reasons for using the kind of convergent exposition of content and questions that is clearly evident in the above episode.

1. Proper learning was enhanced if a student learned a few concepts at a time and learned these concepts in a clearly recognizable serial manner. Digression not only fragmented the topic at hand into many sub-concepts, but also introduced many differing concepts so that at the end of a lesson, both the teacher and the student were unsure of the main gist of the lesson.

2. Convergence discouraged fragmentation and devolution of sub-concepts thus making it easier for the teacher to “get on with the prepared lesson”. Coverage of planned lesson content minimized teachers’ feelings of exasperation and helplessness in case the class loses periods due to various factors.
Searching for the Answer

A characteristic of questions by Lloyd, Charity and Dalia was the frequent occurrence of a phenomenon which Campbell (1981, 1984) has described as "going for the answer". This phenomenon was only rarely observed in Lydia's classes. During question episodes there were many occasions when teachers wanted a specific answer, often a technical word or a phrase describing either a reason or a condition for some phenomenon. The use of this instructional technique was interesting in two aspects. First, the technique was often instituted when a teacher was hard pressed for time, and yet he wanted students to participate in building the lesson content by answering questions. Second, the technique, regardless of other conditions existing in the class, was in actual fact, extremely time-consuming. Teachers had explained that the purpose for 'going for the answer' was to enable students to get a correct answer, usually a technical word, a definition or description. Teachers were generally hesitant in using ordinary language to describe biological phenomena, arguing that students had a tendency either to generalize beyond the limited use of the common expression, or to stick to that common expression even though they had later, learned the technical expression. The solution, Dalia had explained, "is to ensure that you give them the correct terminology or expression the first time and that you insist on its use thereafter".

The phenomenon of going for the answer was not only a time-consuming technique but often undermined the quality of the very processes of student participation which its use was purported to support. Invariably, the teacher was tempted to ask many questions, rephrase them several times to the point of triviality and give increasingly more obvious clues, not only to the correct mental processes students were expected to use to obtain the answer, but also to the nature of the answer itself. An episode from Dalia's Form 2 lesson on Germination, reveals these increasingly obvious clues to the answer.
01. Dalia: We have seen that the seed, when planted can grow and we have named the factors necessary for germination. Who can tell us those factors again? What are the factors required for germination? What does the seed need in order to germinate? Hands-up! Yes Terri?

02. Terri: Water, food and warmth.

03. Dalia: Well, yes. Where does the seed get its food? From where in the seed is food stored? Yes Catherine? What stores the food in a germinating seed?

04. Catherine: The seed cotyledon.

05. Dalia: Yes. The cotyledon, when it is a mono-cotyledonous plant and two cotyledons when it is a... a what? Someone? Ruth?

06. Ruth: Two cotyledons,

07. Dalia: No. The plant. What do we call it if the seeds have two cotyledons? The one with one cotyledon is mono. What is the one with two? Yes Catherine?

08. Catherine: Dicotyledon[s].

09. Dalia: Yes. Dicotyledon. Now we find water being a very important factor in germination. And how does this water reach the embryo? Catherine?

11. Catherine: By going through the cotyledons?

12. Dalia: But how does the water get to the cotyledons? Someone else? Yes Margo?

13. Margo: It softens the testa during germination.

14. Dalia: She says it softens the testa during germination. Is it?

15. Margo: Yes.

16. Dalia: The water softens the testa and the cotyledons during germination, alright? But when you soak seeds in water they swell. They take in water. How does water enter the seed? Yes? I want hands. How do seeds take in
water? We discussed this last lesson. No books please. Yes? (to Terri)

17. Terri: (Stands up and looks blank).

18. Dalia: By what structure on the seed? Do you think the whole seed – the whole seed coat takes in water or there is something else? Yes? (to Margo).

19. Margo: Through the seed scar.

20. Dalia: Not the seed scar. But you are close. Yes? (to Margo)

21. Margo: Through the tiny hole near the seed scar.

22. Dalia: Excellent. That hole, what is the name for it? Yes? (to Catherine)

23. Catherine: Through the micropyle.

Commenting on this episode, Dalia had pointed out that while it was true that she was looking for specific answers, the information in the lesson also served to revise concepts that students appeared to have forgotten. Dalia also pointed out that when a teacher gave a concept to a class the first time, he might put too much emphasis on describing the whole process, for instance, germination, but ignore to emphasize key subconcepts or words that are crucial to the process. In this situation, going over the content and zeroing in on these key words and subconcepts helps the student to master the total meaning of the topic. All teachers concurred with Dalia. Lloyd pointed out that teachers had to impart specific words and phrases during teaching, because it was such words and phrases that gave biology its character. Although teachers were concerned about the amount of time it often took to solicit from students either the correct technical word, a complete definition or a full description of a concept, they pointed out that it was better to give students the true and full meaning of concepts than to leave them with vague descriptions.
The foregoing discussion has shown the diversity of teacher perceptions regarding the functions and accomplishments of questions they thought were for building lessons. It was also evident from both the lesson excerpts and discussion that each teacher’s perceptions shaped the way she or he instituted and evaluated the effectiveness of the instructional techniques that included lesson building questions.

**Lesson Assessing Questions**

Teachers pointed out that student answers to lesson building questions frequently gave teachers an idea of how well students knew the information required by the question. But teachers had to ask specific questions to evaluate: the actual level of understanding by students, i.e., assessing learning mastery; and the progress of student accomplishments of various learning procedures and tasks, i.e. assessing learning procedures.

**Assessing Learning Mastery**

Teachers stated that they generally, used one strategy to assess the quality of student learning, that is, they asked questions at different levels of difficulty to see the proportion of students who knew the correct answer. However, since it was not possible to get an answer from all students, the teacher’s overall assessment of learning mastery depended, not so much on the number of students giving correct answers, but on how many students raised hands probably, to indicate that they were able to answer the question. Teachers were well aware that this expectation was in itself problematic simply because students might raise hands for reasons that might be quite different from those perceived by the teacher. Lloyd, for instance, stated that when he asked a question he expected hands-up from, “Any student who has something to say, any student who wants to try, and anyone who knows the answer.” Yet, Lloyd insisted that in forms 1 and 2, “the chances are very small that, if a student does not think he knows the answer, that he will put up his hand”. Teachers argued that since students in forms 1 and 2 were still very self-conscious, they valued being correct, and
Dalia and Lloyd explained that, depending on the complexity of the question, they expected different degrees of hands-up. According to Lloyd, "if I ask a simple question then my purpose is to ascertain that it was really simple. The more hands I see, the better my prediction. Moreover, I want to get students to get into the habit of owning up to the state of their knowledge." Yet the teacher directive, "I want more hands," must have had the tendency to force some students who were unsure of the correct answer to a question currently on the floor, to put up hands. This might therefore, give a teacher the wrong impression regarding the number of students who had really mastered the lesson. Teachers insisted however, that this did not happen in forms 1 and 2, where students were very

Teachers discussed a subtle contradiction - at least from the perspective of students - as to the 'real' purpose of raising hands. Not only did teachers often select a student who had not originally raised his hand, but quite often, teachers selected a student who had totally refused to raise his hand. Lloyd pointed out that, "if the question you asked was simple, then you wish to ascertain that those not raising hands don't really know the answer. That's why you pick on someone who has not raised his hands. Now, if he gets the answer correct, then you know he has been pulling your leg." In addition, there was a tendency for teachers to demand for "more hands" and subsequently invite the whole class to work on the answer together. The invitation to the class to work on an answer together was often offered soon after the teacher had disapproved "chorusing". But Lloyd explained away this apparent contradiction this way: "when I ask for more hands-up, I don't mean for students to chorus or discuss among themselves. All I want is to gauge the number that knows the correct answer. When I invite everyone to work on an answer together, all I mean is that all students should be ready, since I can pick on anyone to give part or all of the answer." Whether or not in selecting "anyone" the teacher kept in mind those students who had not raised hands, was not made clear. What was clear through observation, was that whenever students were invited to work together on an answer to a question, they soon got tired of the unpredictability of the teacher's strategy of picking on anybody,
and without further directive, student would start to raise hands, even though the original task might not yet be completed.

But Lloyd emphasized that if he selected a student who had not raised his hand to answer a question, it was rarely a random choice. Lloyd had three categories of students from whom he picked individuals in order to evaluate mastery of learning. First, if a question was really very simple, Lloyd would pick on a low achieving student - because he was quite certain the student would know the answer. Second, if a question was difficult, he might pick on a very bright student in order to get a correct answer - so that Lloyd may get on with the lesson. Third, Lloyd would sometimes, pick on what he described as "regressing students". Lloyd stated that in the research class, he had a few regressing students, for instance Mark. This boy had been a bright and active class participant in Form 1. His academic performance had started to slip after the second term of first form. During three school terms in Form 1, Mark's class position had shifted from 7/39, 17/39 to 25/39. In Form 2, Mark's class position had slipped even further down to 27/39 and 31/39 during first and second terms, respectively. Lloyd explained that in Mark's case, it had been difficult to pinpoint the source of his problems until it had been discovered that Mark was spending less time on his assignments and class work since, "he had become the campaign manager for school candidates for the chairmanships of various clubs and societies." Teachers had been advised to talk to Mark outside class so as to try to get him to see the cause of his problem. Therefore, in fulfilling this school-wide policy of encouraging regressing students, Lloyd stated, "I try to keep an eye on him in class. I throw some easy

Assessing Learning Procedures

During the teaching-learning process, students had to participate in several activities such as carrying out experiments, observing specimen, making drawings, writing notes and completing short quizzes. As students engaged in these activities, teachers constantly posed questions such as: "have you finished?"; "have you got that?"; and " are you with me?"; in order to assess how closely
students were keeping to the teacher's pace of exposition of content. For Lydia, for instance, this type of assessment was very important as she had to give students sufficient time to take their own notes after she had discussed a particular set of concepts. Similarly, in Charity's class, students were given time to write up experimental work and to prepare diagrams and drawings. Teachers stated that they had a general idea of how long it took students to make diagrams, observe specimen and write notes, so that the function of procedural assessing questions was not to canvass a yes/no answer. The real function of these questions was to control pace and noise, not only of those who had finished the assigned work, but also of many students who tended to talk while working. Lydia's class was particularly prone to this latter problem, and one of her most frequently used expressions during monitoring of student activity was, "you know you have not finished, but you are talking for some reason."

In Lydia's class, it was observed that one of the most frequent reasons for student talking was that students tended to ask each other to decipher the abbreviated notes made by Lydia on the blackboard, which students were expected to refer to in order to construct their own notes. Lydia said that she was generally, wary of students talking during note-taking, stating, "I cannot separate those who are just gossiping, those asking for help and those simply asking others to read a word for them from the blackboard". To curtail this type of talking and reduce uncertainty on her part, Lydia kept a continual stream of monitoring questions. She said that she did not think that the questions were a constant interruption to student concentration, since she believed that many of them needed the questions in order to evaluate their own pace. But Lydia admitted that sometimes, instead of using her assessment of whether or not all students had finished a task, so as to decide on the next step, she would decide to go on with the lesson due to what she described as pressure of student gestures.
"Some of them (gestures) hit you hard. Some signs and postures are very discouraging, e.g. putting both hands on cheeks and both elbows on desk, sleeping on desks. This is terrible. The way they sit while writing! The screeching of stools, whispering, dropping rulers and mathematical sets of instruments - I try to correct. But it is difficult, and if you notice someone busy writing or reading, but sitting poorly, you decide that since she is working, let me not disturb. But generally those who have finished wait a bit for others. I believe it encourages patience. They will fidget, but I have to control it. However, sometimes it becomes too much. Then I will go on with the lesson, since there is little point waiting, as the noise and fidgeting will have disturbed everyone including those who have not yet finished."

Dalia had characterized Lydia's explanation as "unbelievable", adding, "why do you allow them to go that far? Surely, if I feel students should keep quiet, they should be able to do it. Yours - I don't know. I think you have spoiled them. You are too soft. They take advantage of that." Dalia explained that once in a while, she monitored student work progress by questions such as: "have you finished?; and "how many people are still writing?"; but she added that she made it absolutely clear to students that talking before, during and after completion of work was totally unacceptable in her class.

Questions to Harness Student Alertness

Lydia's statement quoted above suggested a problem that was faced by all teachers, namely how to keep the students motivated and alert particularly, in the non-practical classes. As Dalia pointed out, "you cannot expect interest to prevail all the time - because some content is, by its very nature, boring. So sometimes you need some injection of special motivation. But it is difficult to find what works for all students". Teachers stated many times that questions to build lessons or to assess learning mastery were really for the purpose of keeping students alert. As Lloyd once explained: "I know how to catch those not paying attention. I will describe something. Then without posing or changing the tone or pitch of voice, I will ask a question. Those who were not listening will not be able to give the correct answer to the question or repeat the question itself". Dalia pointed out that she often had to resort to
asking undirected questions in order to encourage alertness in the whole class, adding, "if students learn that you always identify a student before posing a question, they will soon decide not to listen to the question itself."

In addition, some teacher requirements that students stand up while they are answering questions although often thought of as a practice to encourage respect, was apparently, for the purpose of harnessing concentration, not only of the speaker, but also of the rest of the class. Both the waste of time spent by students in 'getting to their feet', and the noise generated as students pulled and screeched stools, which this practice entailed in crowded classrooms, were considered by teachers, as a small price to pay for the effect it had of "awakening everyone". Moreover, standing up had another purpose as Lydia explained: "it is difficult to understand what they say when they remain sitting. They simply tend to murmur or chorus. So I want to have one person clearly identifiable as the speaker".

Only Dalia and Charity had a class rule requiring that a student who had failed to answer a question correctly, should remain standing. Both teachers believed strongly that in many cases, students got answers wrong not because they did not know the correct information, but because they rarely listened properly, to classroom discussion and questions. Therefore, to encourage students to be more attentive, a punishment was attached to any failure to get the correct answer. Lloyd and Lydia, however, considered the practice as a triple punishment. They pointed out that in forms 1 and 2 a student will already be very embarrassed by giving an incorrect answer, and that this should be regarded as sufficient punishment. Moreover, Lloyd and Lydia did not consider standing as a corrective to the problem of lack of concentration and attention, asserting, "the students will become more self-conscious while standing and will in fact, listen less". Since students who were standing had to continue writing, not only were they likely to block both the teacher's view of some students and vice versa, but students who were standing were likely to develop poor postures, produce shoddy work and create problems in situations where teaching-learning
resources had to be shared. For these reasons, Lloyd and Lydia said they preferred to let students sit down even after they had given wrong answers.

**Summary and Conclusions**

From this discussion of teacher perceptions of the purposes for asking questions, three main points have emerged:

1. Asking of questions by teachers during lessons although highly dependent upon contextual factors, serves several academic and social functions. Although the three major functions, namely, lesson building, assessing mastery of learning and harnessing student alertness would appear to embrace worthwhile goals, such goals are likely to be unattainable in many classroom situations.

2. Teachers do not normally ask particular questions that serve a limited number of possible functions. Rather, depending on the context in the class as continuously evaluated by the teacher, several purposes may be served by a single question.

3. Teacher practical theories and perceptions regarding the nature of the teaching-learning processes, the quality of the learning abilities and motivation of his students, influence, to a high degree, the type of functions that the teacher might ultimately perceive his questions to serve.

These points suggest a number of issues concerning the validity of asking questions as a teaching-learning technique. Since shortage of time appears to be a severe limiting factor in attempts to 'cover the syllabus', it would appear that teachers should spend as little of this time as possible on a technique which takes a lot of time; rarely achieves specific purposes; and is more likely to be used for the wrong reasons.

Curriculum developers and teacher educators frequently exhort teachers to use questions in order to involve students in the teaching-learning process. It would appear from these discussions that since the definition of students' participation is itself problematic, the full value of using questions as a participatory technique can be realized only after teachers have deepened their
understanding of contexts, beliefs, perceptions and practices that determine classroom participant structures, within total school contexts. In the following chapter, the likely fate of instructional innovations undertaken by teachers who had only a superficial understanding of the contexts of their schools and classrooms, underscores the indespensability of a deeper understanding of teaching-learning contexts to the improvement of instruction.
Chapter 4

IMPLEMENTING INSTRUCTIONAL CHANGE

"The sermons of the headmistress on teaching are bound to fall on deaf ears because she always puts the blame where it does not belong" Charity (1984)

Introduction

In Chapter 1, some of the procedures and factors that were crucial to establishing meaningful participation by teachers in the project were discussed. In chapters 2 and 3 the content of teacher discussions during the seminar were presented. Those three chapters were dominated by a presentation of teacher observations, comments, statements and perceptions. In this chapter, devoted to the implementation of instructional change in classrooms, although teacher perceptions and comments form a substantial part of record, they are considered within the broader context of the researcher's own observations and interpretations of the implementation effort. In discussing various elements of each teacher's implementation strategies, emphasis has been placed on analyzing how the school milieu, the social organization of classrooms and overall teacher instructional strategies, all interacted and influenced the structure, success and stability of new instructional techniques. Data collection and interpretation were guided by four questions:

1. Did teachers develop concrete idea of various instructional changes needed in their classrooms, and set out plans to implement such change?

2. What instructional changes did teachers implement? How did they implement such changes and for how long?

3. Since the instructional changes that were considered for implementation had been suggested to teachers during seminars, was there evidence that teachers had a clear notion of what techniques
they wanted to change and what steps they would follow to bring about the

4. Was there evidence that teachers had, through discussions, reached new levels of understanding and interpretation of various contexts in their schools, and had catered to such contexts in evolving the implementation strategy?

Development of Ideas for Change

Throughout various seminar discussions, teachers had been encouraged to speak their mind, but the implicit understanding that each teacher would be free either to heed or to reject suggestions for change from his colleagues remained ambiguous. Teachers were expected to help one another not only by describing individual perspectives regarding what was good or bad practice, but also by suggesting alternatives to current perspectives and practices. This was not always easy to achieve as the following incident illustrates.

During a seminar in early 1984, teachers discussed the quality of student passes in various subjects on public examinations since the 'O' level results for 1983, had just been released. The schools of Lloyd and Lydia had obtained good results while Charity's school had poor results. Dalia had commented that the results in her school had been reasonable in view of the initial abilities of students and the quality of facilities supporting teaching. Dalia had further explained that the nature of the mock examination questions was crucial in order to alert students as to how well they might perform in a real examination. Lloyd suggested that the mock examination was not as important as the kind of teaching and revision that was done as a follow-up to the mock examination. Lydia said that the most important factor was the type of questions set in the mock examination since these questions gave true practice to students on how to answer the real examination questions. Charity had suggested that the reason why students in her school had performed poorly was perhaps because she and staff in her department did not know how to set proper mock questions. After inspecting and
comparing the 1983 mock examinations question papers from all schools, Charity had exclaimed, "these are the very same questions that we set for our girls. Why don't ours do well? These are the very same questions we had."

Teachers were quite surprised after they had compared the mock questions across schools as well as the mock questions with the 1983 public examination questions on biology, noting that:

1. The questions for the mock examinations from all four schools covered 25 different topics, and that there were only the information requested was unique to a particular school.

2. In only Charity's school was there a question that bore a relatively close resemblance to a question in the public examination papers.

Teachers debated the merits and demerits of the various questions in reference to what Lloyd, Lydia and Dalia had said about the crucial role of the mock examination, but they failed to reach a consensus on what could be defined as "the most important function of the mock examination". Finally, Charity stated, "obviously, with our students, I don't think that the mock matters any more. Even if you probably gave them the real public examination questions as the mock, they would still mess up both examinations."

At this point the three other teachers "attacked" Charity insisting that the reason why students in Charity's school were not performing well in examinations was because, "teachers like you give-up on the students long before the students give up learning". Lydia insisted that teachers at Charity's school did not attempt to help students as much as possible with both their social and academic problems. When this debate had subsided, Charity insisted that teachers should view tapes taken in class in order to appreciate some of the problems in her classes, adding, "you should see for yourself." Teachers had viewed a compiled tape consisting of eight segments from lessons during four consecutive weeks of observations. I explained to teachers that in each of the eight lesson segments, Charity had threatened a student, Faith, with expulsion from the "next" biology lesson, unless Faith brought her notebook to
class. I further told teachers that since up to the last lesson taught, Faith had not brought her notebook to class, they might wish to suggest ideas on how Charity should deal with the problem during her next lesson. The following is a verbatim excerpt from the discussion among teachers that followed viewing of the tape.

01. Dalia: Why doesn't she have a book? I could not hear very clearly all her reasons.

02. Charity: She says she lost it.

03. Dalia: Ask her to buy a new one.

04. Charity: That is what I have been saying to her in every lesson. But she says her mother says she has no money.

05. Lloyd: Three shillings! And a parent doesn't have that much for a book?

06. Charity: She is lying, of course. But what else do I do?

07. Lydia: Why don't you get her a book from the school?

08. Charity: How?

09. Lloyd: Don't you have a system where you give students a new book if the old one is finished?

10. Charity: We do. But I have to sign in the back of the old book that is finished as evidence. But Faith does not have a finished book.

11. Lydia: Why don't you explain to the head of school the case and get her to get Faith a new book from the school funds?

12. Charity: Recently, one girl lost all her household property, including her books, in a fire. I went to the school store and signed for two new books for her, with the reason clearly stated in the record. When the head of school saw the store record, she called me and told me the school cannot afford to give away school property on such flimsy excuses. The head said I should not repeat it, and I am not going to repeat it, because then I shall have to pay for the books,
13. Dalia: If Faith has an older book, take that one.

14. Lydia: But it will already have a signature if she took it to the store to get the next book.

15. Lloyd: Tear off nicely the last page (laughs) and sign the next page again.

16. Charity: The storekeeper, they count the number of pages at the store.

17. Lloyd: Actually, I was joking because we too count the number of pages. If they don't add up, the student pays for the new book.

18. Dalia: Buy her one yourself.

19. Charity: How many books will I buy? This sort of thing is very common in our school.

20. Lloyd: So what are you going to do if she has no book next lesson?

21. Charity: I will send her to the deputy, who I am quite certain, will do nothing much. The deputy will just send her back to my class without a book.

22. Namuddu: So what other advice can you give Charity? She has a class on Monday morning.

23. Lydia: I think in some of these schools, the best thing is not to advise since we don't really know what else is going on, which is not on tape.

During that seminar, the matter was left at that point. At the next seminar, I told teachers that after I had previewed a tape containing the above discussion, I had concluded that while each of the teachers had 'given advice' to Charity, depending on procedures and mechanisms that were practical in their individual schools, practices which made sense to the teacher, they had not considered how such advice would fit into a different school setting. During subsequent review of the same discussion, teachers kept on commenting, "Did I say that?" By the end of the review, teachers appeared to have arrived at new state of consensus, namely, that
they would disagree with each other, question each other's practices and beliefs, "attack" each other, but they would not try to force each other to do something a teacher did not consider right from his perspective.

Teachers also discussed the role of personal initiative. We described facts of "habit" that might become blinders to possible alternatives to current perspectives and practices and attempted to draw differences between expressing opinions and giving advice. We made it clear that expression of differing points of views was mandatory but choosing to act or not to act upon any expressed opinion was an optional and voluntary exercise. In addition, we emphasized the fact that even in a single classroom, the nature of good practice would not always be the same, and that there was probably a continuum from good practice to bad practice where the line separating good practice and badness, might often be quite fine. To give an example of this continuum, teachers reviewed, several compiled episodes on student questions in order to assess the validity of a hypothesis I had defined, namely, that the more questions students ask, the better the lesson.

Teachers first viewed six episodes from lessons by Charity and Dalia. Using the hypothesis, teachers described the lesson as bad since there were very few questions. Teachers were encouraged to advise Charity and Dalia, and subsequently, several strategies such as demanding questions, giving question-generating assignments, holding brainstorming sessions and challenging students with problematic situations were suggested. Lloyd told Charity and Dalia: "you are not working hard enough to get students to participate in the lessons". The two teachers defended themselves explaining that they had tried to involve students in lessons, but Lloyd and Lydia said they did not agree and suggested they should try harder. Lloyd concluded the discussion by asserting, "all that these students need, is encouragement, then you will have many more questions than you can cope with. I do not agree that good or bad manners and brains have anything to do with asking questions."
Teachers then viewed a set of three episodes from Lloyd’s lessons. These were rated good since, as Lydia pointed out, “there were quite a few questions”. But both Dalia and Charity were somewhat surprised that there had not been more questions. Dalia said to Lloyd, “after seeing yours, I don’t feel so bad”. Teachers then viewed two segments from Lydia’s lessons. In one segment, students had asked 32 questions in 20 minutes and Lydia had attempted to answer them all one by one, as well as often asking other students to give their own opinions. After viewing this segment, Lloyd had asked Lydia, “what was your planned lesson? These girls have kidnapped your lesson”. Lydia insisted however, that she did not mind the barrage of questions as long as the students were learning. Dalia thought the girls had gone too far, asserting: “it is sheer cheek; and would be unacceptable in my class”. Charity said she wished she could export her students from Urbana to National in exchange with Lydia’s. Although Lloyd insisted the student questions were too many, he said that he had found the responses from the girls fascinating, “I think girls are much more livelier to teach. They are creative. They are fun. Your Form I are like my Form 4 class. The students constantly remind me, ‘sir, you have not yet answered Tom’s question which he put to you five minutes ago’. Only a week ago a student interrupted my explanation to tell me that another student had put up a hand and had a burning question for the last five minutes. I have a special relationship with this class. They are very close to me”.

Dalia who had been listening to Lloyd’s animated explanation with a large measure of scepticism, said that she thought all that was too emotional to be useful in her school situation, adding, “you would think otherwise if you were with girls. They would take advantage of you. They demand special treatment.” Charity said that she was only amazed to hear that there were students in fourth form who still enjoyed learning even in the third term of their public examination year, adding: “ours give up long before that - they just sit in class and day dream - that is, if you can get them into class.”

Lloyd and Charity ranked Lydia’s lessons as good. But Dalia said that the lessons were bad because even though there were many
questions asked by students, Lydia had failed to control the class. In
discussing what kind of advice teachers could give to Lloyd and
Lydia, teachers pointed out that my original hypothesis that, the
more questions asked by students, the better the lesson, was not
"always" valid because, as Dalia explained:

"I would advise Lydia to control her class so that she can teach.
In fact I don't think I still feel as bad as I felt earlier, because
Lloyd's lesson, which I think was good, did not have many
questions—only about six—by students, and I think that is just right.
But Lydia's lesson, that's a discipline problem. Students should be
taught to control their asking of questions. My advice, well to me,
I will try to get my students to ask questions, a few at least. Same
for Charity. Lloyd is OK. Lydia well, teach more."

When Dalia was asked whether or not she contended that students
learn from their questions and answers, she explained: "Of course
they learn, but not from that many questions. Who now knows what
was taught in that class? It was all bits and pieces". Lydia said
that she was not going to take Dalia's advice because, as far as she
was concerned, she had taught. She added, "OK, so there were many
questions. And I don't know what to do. But what you are saying is
not right. If your students put up hands, would you ignore them? In
fact when you ignore their hands and questions, they become upset
and fidget even more."

Teachers had discussed several other labels of student behaviour,
such as; dull class, active, noisy, lazy, motivated, bright and several
others, by reviewing lesson episodes similar to those quoted above.
Teachers came to appreciate that the meanings and interpretations
of these concepts, which they had always taken as self-evident and
theoretically defined as umbrella terms for behaviour in general
school situations, had fine re-definitions quite unique to particular
schools and particular classrooms. Student behaviour in asking too
many questions, for instance, which had been interpreted as a good
learning technique by the classroom teacher, was regarded as a
purely discipline problem by another teacher. Similarly, what Lloyd
regarded as closeness to his students, had been interpreted by Dalia
as unnecessary emotional attachment.
Discussions and comparisons of this nature led teachers to a deeper understanding of 'good' and 'bad' practices in classrooms. Equally important, teachers came to evolve a broader definition of "good" and "bad" schools. At the beginning of the discussion Lydia had given teachers a guiding theme on this somewhat sensitive issue, when she had stated, "to many teachers, teaching in a good school is not really palatable. There is too much work." During a later seminar where teachers grappled with the question of whether it was easier to teach in a high achieving or a low achieving school, Lloyd had retorted, "I would like those people who claim that the kids in good schools just pass their examinations, to come and work here for a week. They would run away as soon as they realized that it is a 24 hour job." But was it true that there was more work in good schools and less work in poor schools?

It took a long time to gather data and information to help teachers define the concepts of hard work and much work. This was partly because at the beginning of the research project all the so called "good" schools were boarding while the so called "poor" schools had only a small group of boarding students and the other school a day school. But by the middle of the project, a very large proportion of students at District were boarders. The case of District, enabled Dalia to keep track of the "increasing amount of non-academic workload" created as the institution moved from a predominantly day school to a boarding school. This experience provided teachers with deeper insight into the definition of hard work, at least, at three levels, so that they could debate meaningfully on which aspects of this work influenced students outcomes. First, teachers were able to identify work that was done by teachers regardless of whether the school was boarding or day. Second, teachers identified work that was done by teachers specifically because the school was either boarding or day. Third, teachers identified "extra work" in boarding and day schools. Dalia's experiences were useful in cataloguing the emerging responsibilities of both teachers and pupils as more and more students became boarders. And in Dalia's own situation, the range of responsibilities was probably far greater than would normally have been the case. Because the school had few staff members who were resident on campus, duties and
responsibilities which would have been shared among 30 teachers were being shouldered by only 8 teachers.

At Urbana where school started at 7.45 a.m. and closed at 4.00 p.m., all teaching, duties and responsibilities had to be undertaken during this short period when students were in school. For instance, clubs, societies, prep, assignment completion, games, and a modicum of housechores all had to be done either before or after class. Teachers therefore, arrived at a consensus, that a school whether boarding or day, demanded hard work from teachers, but that the definition of hard work varied within and across schools. After teachers had examined the purposes of the three levels of work, they were convinced that a ubiquitous characteristic of all schools was the "creation" of unnecessary extra work for staff and that most of this created work was often counter-productive to teacher efforts to do academic tasks. But teachers appreciated the fact that the "created" work did serve a purpose in particular school contexts. Teachers arrived at a general conclusion, namely, that the more a school worked to reduce, simplify and co-ordinate this "created" work, the greater were the chances, that teachers would concentrate on academic tasks, with the result that the school would most likely improve on the scale of academic performance - becoming a good school. But all teachers agreed that work or hard work, was sometimes as emotional as it was physical. What counted was that at the end of each day, the teacher was always tired. If, on one hand, the work that had sapped a teacher's physical and psychic energies was for the benefit of pupils - in class and outside-teachers said that they felt good about it. If on the other hand, the work that had exhausted them and taxed their nerves had been for the benefit of an administrator's file, while to the teacher it was still work - hard work- teachers looked upon it as ultimately more exhausting work than classroom work.

By reflecting on similar issues within the wider context of schools, it was possible for teachers to decide on particular changes they wanted to make in their current instructional strategies. Both the
process of selection and implementation were quite fuzzy as is clearly shown in the following section.

**Implementing Instructional Change**

In the general concept of the project, every teacher in the project was implicitly expected to implement some instructional change but only after being convinced that such change was necessary and that it would make a difference in the classroom. Yet it was important that teachers should not be made to feel that they were under pressure to implement change or that the quality of their implemented changes was constantly being judged by the researcher. Against this background, the following assumptions were made regarding teacher willingness to implement instructional change:

1. If a teacher was observed not to have attempted to implement any of the alternative techniques suggested by his colleagues regarding his instructional strategy, it was assumed that either the teacher had not been convinced of the usefulness of such alternatives, or he had simply not wished to implement change.

2. After teachers indicated during the research and seminar evaluation exercise, whether or not they were planning to undertake defined instructional changes and when and how they were intending to go about the task, teachers were not directly interviewed about instructional changes. It was assumed that if the implemented changes were real, it would be possible to identify them during normal classroom observation.

3. If a teacher was observed to have implemented instructional changes, clarification regarding the implementation strategies and the stability of change would normally be sought during seminars, pre-active, and post-interactive interviews as general discussion.

**Instructional Techniques Targeted for Change**

During discussions and video tape analysis, teachers isolated various instructional techniques that individuals said they wanted to either initiate or modify in some way. Chart 2 below lists all instructional techniques that the four teachers, Dalia (1), Lydia (2),
Lloyd (3) and Charity (4) identified as requiring some form of change in their overall instructional strategy. The actual changes in instructional techniques that were implemented by each teacher are shown in column 2. The period during which the implemented changes were observed to have been sustained as part of the teacher's instructional strategy is reported in column 3.

Altogether, 32 instructional techniques were considered by teachers as possible targets for either initiating or modifying in various classrooms. But only 15 of these techniques were actually implemented and tried out for various periods during the life of the project as shown in column 3. The chart also reveals that even though fewer techniques were considered for initiating as "new" (11) as compared to those considered for modification (21), teachers actually implemented about an equal number of instructional techniques from each category. In general terms, Dalia identified nine instructional techniques four of which she considered for initiating in class while five were for modification. In actual fact, she implemented three out of the four "new" instructional techniques and modified one out of the five she was already using. Lydia identified only one "new" instructional technique—using the school compound as a learning resource—which she wanted to initiate, but considered four techniques for possible modification out of which she was able to implement three. Lloyd implemented two instructional techniques he identified as "new" and three techniques out of the five he wanted to modify. Charity was able to implement three out of four new techniques and modified only one out of seven which she had identified as requiring modification. What was the nature of the implementation process for each of the four teachers?

**Dalia's Instructional Changes**

Dalia was observed to have identified four main weaknesses in her overall instructional strategy. First, she said she was not devoting as much time as possible to the systematic planning of her lessons. By systematic lesson planning Dalia meant, "I don't think, I am able to judge very well, what we are able to do in a particular period, in view of what I end up doing". Second, Dalia said that it was often difficult for her to isolate objectives for a specific lesson within the broad goals of teaching particular topics. Third, she said that she was spending too much time on revising content of previous lessons before embarking on a new lesson. Fourth, as will be recalled from discussion in Chapter 3, Lydia, Lloyd, and Charity had
described Dalia's class as generally very inactive so that Dalia wanted to get the class to become more active.

In actual fact, Dalia's idea of improving her lesson planning was the result of two frequent comments made by her colleagues on her video lessons. In the first instance, quite a few lesson episodes had shown Dalia announcing a series of objectives to the class at the beginning of a lesson, which were then followed by lesson activities or instruction which had little to do with the objectives. For instance, at the beginning of a lesson on *Germination*, Dalia had announced, “today we are going to watch the process of germination”. The rest of the lesson had however, been spent on revising the structure of seeds and on planting seeds. In another lesson, with the objective of describing differences between insect and wind pollinated flowers, the largest proportion of time had been spent on describing the characteristics of mono-cotyledonous plants. In the second instance, Dalia was rarely able to “cover” her planned lesson. As a result of these two comments, Dalia had felt that she had to do something about her lesson planning.

A common characteristic of video tape segments from Dalia's lessons was the large number of students caught by the camera staring absently at either the camera or outside, while Dalia was talking. Moreover, many students, particularly the girls, seemed to require a certain amount of coercion in order to get them to start on assigned practical work. During first form, Dalia's class had consisted of only girls. At Form 2 however, half the number of girls had been moved to a different stream and their places had been taken up by boys. It was observed that girls often sat quietly by themselves and appeared to fear mixing with boys during practical work. Lloyd had at one point asked Dalia: “when do your students talk? Do the girls talk at all? Dalia had replied, “they are too quiet. I don't know what is going on. But something is wrong with that class. They are too quiet”.

Subsequently, Dalia had implemented four instructional changes namely: systematic lesson planning; motivating students to ask questions; encouraging students to interact with one another and to
use each other as a resource during practical work; and encouraging students to use specific cognitive processes in processing and learning new information. Generally, Dalia attempted to get students, particularly girls, to be more active during practical work. Dalia did not talk about the various instructional changes she had implemented but it was observed that:

1. Whenever Dalia attended pre-active and post-active interviews, she would ask several questions regarding lesson planning, and the effectiveness of various new lesson sequences I had observed her using during lessons.

2. Dalia would prepare fresh lesson plans for all lessons including lessons she taught in language and in non-research biology classes. Her lesson plans were more systematic in outlining and sequencing the major concepts in a lesson.

3. Dalia had become very conscious of using class time and would constantly review her lesson plan during the teaching-learning process, presumably, to ascertain that she was sticking closely to it in order to be able to cover what she had planned.

4. Dalia had instituted a more comprehensive monitoring system of students whenever she assigned students group or individual tasks.

5. Dalia would attempt to evaluate lessons by asking questions at the end.

6. Dalia would demand more systematic and detailed work from the students.

With the exception of a file of lesson plans, she did not have a record of her new or modified instructional techniques. Beyond these in-classroom changes, Dalia was observed spending more time in the staffroom reading, at least, three different reference books before writing down her lesson plans. She was particularly thorough in preparing the laboratory for practical work, collecting the needed materials, improvising quite a lot of apparatus for experiments and double checking with the laboratory technician regarding specimen.

But the actual implementation process was observed to be quite haphazard. It was quite obvious that Dalia implemented changes she
selected, more or less, at whatever stage she saw fit. It did not appear that she had a definite plan. During the same period, Dalia had also become very conscious of being video-taped. She had pointed out that she "hated it", whenever I appeared to tape a lesson when she suspected she was not as prepared as she would have wished. Similarly, she would get quite upset whenever she felt she was quite prepared for her lesson and I would either not show up or would come without a camera.

Dalia's Reaction to Student Responses to Changes

It was observed that student responses were a major source of consternation to Dalia as she constantly tried to evaluate the effectiveness of her instructional changes. This was particularly so with regard to her effort to effect an overall change that would bring about new modes of interaction among students, conserve time and reveal the positive results of systematic lesson planning. What Dalia found however, was that the student pace of activity was too slow to accommodate her own perceived sense of the kind of interaction needed among students. What she therefore, did was to section each lesson into such tiny sequential segments, so that she could then monitor student activity effectively, while at the same time conserving time. For example, during a lesson on the structure of the seed, Dalia and the class performed the following tasks.

1. Dalia demonstrated how to study a soaked bean seed, (3 minutes) draw it (3 minutes) and label the diagrams(3 minutes).

2. Students performed the task (10 minutes), as Dalia went around the room monitoring progress.

3. Dalia demonstrated how to squeeze the seed (3 minutes) and write down observation (2 minutes).

4. Dalia demonstrated, using very detailed instructions how to split the seed longitudinally (3 minutes) observe the inside parts( 5 minutes) and what to draw ( 2 minutes). Then she resumed monitoring.

5. Students performed the tasks (15 minutes), as Dalia monitored progress.
6. Dalia demonstrated how to remove the embryo from the cotyledons (5 minutes), identify the plumule and radicle (5 minutes) and draw the embryo (2 minutes).

7. Students performed the tasks (10 minutes), as Dalia monitored progress.

8. Students had just started looking at a maize grain in a similar manner, when the end-of-class bell rang.

Looking at the above steps of the lesson, it is evident that examining one specimen had taken 80 minutes. Dalia had explained earlier that the objective of the lesson was to identify the key structures of seeds. Students had therefore, made six large diagrams of various structures, but when, during the next single lesson two days later, they were asked to identify the structure called the micropyle, no one had the slightest idea. Why? Jane, the student I had sat next to during the previous lesson, had drawn a full page diagram of a micropyle, and while Dalia talked of a "tiny hole" just above the seed scar, Jane flipped through her notebook containing the large diagrams, but she could not locate one representing a 'tiny hole'.

Increasingly then, Dalia found that the more she 'sectioned' the lesson into smaller and smaller segments for the purposes of monitoring, introducing opportunity for student interaction and effecting proper use of time, the more frequently she had to re-teach stuff she had earlier covered. She often discovered, through evaluative questions, that students had not made the linkages in the content, which she had assumed they would make. Dalia felt frustrated and slowly reverted to her original classroom sequences. I wondered whether it would have made a difference if Dalia had alerted students to the new instructional changes or if she had tried to keep a record of her changes and activities. When at the end of her 'project' I asked why she had abandoned the techniques, she was a bit shocked to learn that I "had been watching" and she said, "I think some of these things are not going to work very well when you have our kind of students."
In the final analysis, however, two factors and probably not "the kind of students" were responsible for Dalia's abandonment of the instructional changes she had implemented, namely the unpredictability of the research timetable and Dalia's increasingly diverse and extensive workload. First, with regard to the unpredictability of the research timetable, each teacher strived to have lessons captured on tape when they believed they had either been well prepared for the lesson or had taught very well. For instance, teachers often asked me to preview specific lessons because: "I think I was alright in that lesson". But because the taping of lessons was unpredictable, Dalia increasingly came to feel that because only the worst of her lessons, were being taped, she would be unable to get me to tape one of her better lessons. Eventually, she lost the motivation to 'stage' lessons with 'special' techniques for me and reverted to her usual instructional strategy.

A more detrimental factor to Dalia's efforts to implement instructional changes was Dalia's increasingly diverse and extensive workload. In July 1984 Dalia was made deputy head of the school. As head of her family while her husband was away, as the teacher responsible for overseeing the boarding section of the school, as deputy head in a school where the school head was frequently absent, and with a heavy workload both in biology and language teaching, Dalia had very little time for pre-active preparation and thought about her teaching. She often had to miss her class while "filling in" for the school head. More than ever before, Dalia had to "catch up", makeup" or "cover" lessons and under the circumstances, it was hardly possible for her to worry about the details of new instructional techniques. Dalia's teaching became more of simply giving content, whenever she was available, than of evaluating how the content was being learned by students.

It was also observed that Dalia's new and elevated status affected not only her classroom work, but also her participation in the research in three subtle but important ways. First, a deputy head of school is an important and senior position in school. And in a co-educational school, as was the case at District, the deputy is often of a different gender from the head of school, so that for practical
purposes, the deputy’s status is seen more as that of the “head section of the school’s students who are not of the gender of the school head. More significantly, at District Dalia’s new status and position meant that she had to implement on a daily basis the school’s total policy as well as administer routines such as executing “big” punishments to students, and censoring student dormitory behaviour. It therefore, became increasingly difficult for students in the research class to continue to regard Dalia as just an ordinary classroom teacher. It would have been impossible for students to ignore Dalia’s directives given at assembly on the need for absolute obedience, conformity and silence in class at all times, in order to become questioners, challengers and visible interactionists during Dalia’s lessons. Inside and outside the classroom, students came to treat Dalia not as simply a biology teacher but as a deputy head of school.

Second, Dalia’s own personality underwent some visible change after she became deputy head of school. The new status and position removed her from the noisy and crowded staffroom to a quiet separate office. But this meant isolation from her colleagues. Perhaps more significantly, Dalia soon discovered - like many administrators are bound to - that “former” friends were not the easiest group of teachers to administer. Dalia once explained in frustration, “I have finally got to know that all my friends are different. I think people are difficult to manage. They want you to let them off just because they are friends”. Obviously, Dalia had to adopt a somewhat tough stance with her friends. This stance might have filtered through to the classroom as earlier mentioned.

Third, it was observed that during seminars, Dalia who had initially been very open and critical of her school’s policies, had become more defensive against any criticism of her school in general and of school administrators in particular, than she had been previously. It was as if she could no longer trust the other teachers, who in turn subtly revealed that they could no longer ‘trust her judgement fully’, even though they never actually discussed the issue directly.
For instance, during the latter part of 1984, the schools' divisional athletics and sports competitions were being played and both the District High and National High netball teams were in the same division. A day before one seminar meeting, the two teams had competed and District had defeated National. During the seminar, Dalia, Charity and Lloyd began by talking about the two teams. Dalia pointed out that the coach of the team from National had not realized that District's team (which was being coached by Dalia) was very experienced. At this point Lydia came in and the following brief exchange ensued:

01. Dalia: We beat your girls yesterday.
02. Lydia: Where? What was it?
03. Dalia: In netball. We beat them.
04. Lydia: Oh! I did not know that! Whom are you playing next?
05. Dalia: These were the semi-finals. We don't know who will win in the 2nd division.
06. Lydia: Oh! You are that high! I thought you were just beginning.
07. Dalia: No! We too can be good at something!

When, two minutes later, Dalia went outside the seminar room to re-park her car, Lydia commented, “she has become a real politician”. Ultimately, Dalia was able to devote increasingly less time to the total research program than other teachers. She had too many responsibilities and sometimes, this created minor irritations to other teachers especially whenever she failed to collect and present various forms of data during seminars. Dalia's case clearly illustrated that since gradual change in instructional strategy require time for planning, implementation and reflection at every stage, combining too many duties is likely to affect the outcome of change. It is quite possible that had Dalia not become deputy head of school, at the very time when she was trying to introduce change in
her overall instructional strategy, she probably might not have abandoned the implemented changes as quickly as she did.

**Lydia's Instructional Changes**

Lydia identified only one "new" instructional technique that she wanted to initiate, namely taking students out more often to learn biology using resources in the school compound. But Lydia actually implemented this technique, only once, for a few minutes during the life of the research project. Lydia was observed sending students out to collect materials. Before students left the laboratory, Lydia had told them that they would have 10 minutes in which to collect different types of fruit. Lydia did not go out with the students as she said she wanted to set up the laboratory for the rest of the lesson. During the first 3 minutes after the students had left, Lydia worked on setting up various stations. Then she became nervous, wondering loudly what the students were doing. Within the next 2 minutes she went out and re-called the students back to the classroom claiming that they were wasting time and gossiping. When she observed that only a few girls had found any fruit she said, "Well you can use my fruit. We have plenty here."

Lydia however, identified four other instructional techniques for modification. Lydia had pointed out on three earlier occasions, that she wanted to encourage students to interact with each other more and use each other as resource during practical lessons, but she again did not implement any noticeable changes in this technique. What Lydia actually implemented and improved upon, were three related instructional techniques, namely: encouraging students to use specific cognitive processes required in processing information when words such as think, imagine, analyze, synthesize, compare etc. are used in teacher questions to students; giving more time to students to think before giving answers to her questions; and encouraging students to elaborate on their answers.

As can be seen from column 3 of Chart 2, these 3 instructional changes were carried through right to the end of the research project. However, why did Lydia not implement one technique which she had said she wanted, abandon another technique after only a few
minutes of implementation, and stick with three other techniques right to the end of the project?

It would appear that Lydia's abandonment or pursuit of a particular instructional technique depended very much on whether or not it would fit into her existing overall instructional strategy. It is not possible to give here even a brief description of Lydia's instructional strategy, but such a strategy rested on at least, two crucial beliefs of Lydia, namely: that she was the most accurate source of biology content; and that a constant 'bird's eye view' of the whole class was indispensable to proper teaching. The technique of using the school compound as a resource during teaching and learning biology was abandoned by Lydia precisely because it violated both beliefs. In the first instance, Lydia could not keep an eye on the whole class while they were out of the laboratory, and she was unsure of the authenticity of student biological information to each other while students were out of the classroom. Similarly, the second technique, encouraging students to be resources to one another, not only violated one of Lydia's beliefs concerning her role as a resource for accurate information but was also probably unnecessary in her situation. Students were already interacting sufficiently with one another so that Lydia probably realized that her encouragement of students on this front, would simply throw the class into chaos. When Lydia had been asked why she thought the students needed more interaction with each other, she had replied, "I am not sure really. I suppose they already make enough noise".

Lydia implemented and carried through to the end of the project, three other techniques precisely, because they were changes that fitted in very well with Lydia's usual instructional strategy, so that they actually demanded very little effort from Lydia, not only to implement them, but also to sustain them. Moreover, Lydia believed that these techniques worked and were useful for student performance in public examinations. When for instance, I asked Lydia whether or not I was correct in my observation that students were giving longer answers to her questions, she replied:

"Oh, I have been really encouraging them to explain things. They are required to do this in the examination and tests, so they should practice it. I know sometimes it is not possible to give more than one
word as answer but I have now decided to ask questions that provoke
them into debate. It is good for them.

Furthermore, Lydia's students had no problems with these modified
instructional requirements since the majority enjoyed talking and
giving opinions, so that these instructional modifications only
helped to refine students' own derived strategies for sustaining
speech and dialogue with Lydia, rather than having her keep them
busy with written tasks. In the final analysis, however, Lydia did
not consider seriously that she needed to change much of anything in
her overall instructional strategy. Even though she sometimes
indicated that she felt exasperated by gaps in student knowledge,
she was not really ready to change anything substantial. She had
once asked me what I thought was lacking in her teaching method.
When I pointed out that I did not think that she used time very well
during the teaching of basic concepts and skills, she was adamant
that changing the pattern of time use would not change anything
with regard to student ability to recall and use these basic concepts
and skills for later work. In certain aspects, Lydia was the most
puzzling of the four teachers. She was much more open about some
of her own feelings about herself, her work, and her pupils than any
of the other teachers. Yet, her absolute belief in the right of
individual opinion often prevented her from expressing her true
feelings about other people's opinions. This meant that while she
was a willing participant, she, more than of the other four teachers,
could in a real sense, "get away without doing anything".

Lloyd's Instructional Changes

Lloyd identified two techniques, namely, systematic monitoring of
student practical work; and use of words such as think, imagine,
analyze etc., to encourage student use of specific cognitive
processes as instructional techniques that he wanted to initiate.
Five other instructional techniques, namely: taking students out
more often to learn biology using the school compound resources;
posing more questions to low achievers; giving quizzes and short
tests to evaluate student understanding of concepts; giving students
more time to think of their answers to teacher questions; and
encouraging students to elaborate on their answers; were identified for modification. Lloyd just like Lydia, implemented mainly those instructional techniques that fitted into his existing overall instructional strategy, except for the techniques on systematic monitoring of student practical work. During viewing of tapes from Lloyd's lessons, his colleagues had told him that he spent too much of his monitoring time looking at work of only those students sitting on the front bench and on the right side of the laboratory. Lloyd had finally admitted that he had been "biased" and promised to change to a strategy that would embrace students at the back. Lloyd appeared to have done some systematic study of the students and the relationship between where they sat in the laboratory and the quality of their general performance, before implementing his new techniques. He explained for instance, that he had found out that the "backbenchers" were mostly students of average ability. The new monitoring strategy that was implemented, was observed to consist of basically the opposite of the monitoring strategy used before, because now, Lloyd almost totally ignored the students sitting at the front of the laboratory, and instead, concentrated on the last two benches. After three weeks of Lloyd's implementation, I had asked Lloyd whether or not, in his effort to monitor the work of students at the back and sides of the class, he had not ignored the front bench totally, and Lloyd had replied, "I know the fellows at the front are serious. They are not interested in wasting time. They don't need my supervision".

During the next seminar, teachers viewed a segment from Lloyd's practical lesson on *The Structure and Function of Wood Vessels*. Lloyd had brought into class cuttings of geranium previously soaked in red dye. The students were required to make transverse sections of the stems, observe these with hand lenses to identify which tissues had stained red and which ones had not, make diagrams of their observations and interpret the meanings of these observations in terms of the tissue functions. The video tape showed mostly activities of students on the first bench, but also made periodic sweeps around the whole laboratory so that the activities at the front bench could be seen in relationship to where Lloyd was and
what he was doing at particular points in the lessons. Briefly, the lesson proceeded as follows:

First, Lloyd was seen at the front bench demonstrating the procedures for the task - all the class was attentive. After five minutes, Lloyd had asked students to collect materials - the stem cuttings, a knife, razor blades, and a hand lens for each group of 4 or 5 students. Soon all students were back at their stations with the materials. The front bench with 8 students had, alone, collected 10 stem cuttings - (other benches had an average of three each), 6 hand lenses (instead of the mandated three per bench) several knives and a boxful of razor blades. After the next 10 minutes, during which the frontbenchers made a lot of noise, Lloyd brought in 4 large mounted hand lenses. He gave one to the front bench and one to each of the other benches. For the next 25 minutes, Lloyd remained at the back of the class demonstrating procedures and helping students to cut sections and view them correctly using the hand lenses.

Meanwhile, at the front bench, a game of 'seek and hoard' was being played by students using the large hand lenses. By this time, the front benchers had divided themselves into three groups, each with two small hand lenses. The problem was to share the large hand lens. Everyone wanted it - but not necessarily for viewing the stem cuttings, at any rate not at first. As the lens was passed and snatched from hand to hand, and tested by various students to magnify nostrils, fingernails, eyes, patches of leaves, watches and other objects, Lloyd did not turn around even though at that point, the frontbenchers were generating enough noise to arouse the curiosity of students on the second bench. At the second bench, Githinji, who was ordinarily a very active student, had managed to 'steal' a second big hand lens from the third bench, while some of its owners had wandered off. But Githinji could not keep the lens on his bench without its owners discovering it. He had therefore, moved to the front bench, and with the help of one of the groups of frontbenchers, had hidden the lens between an erected square of textbooks. Whole stem cuttings were gingerly laid across the top of the structure, and whenever it appeared as if another student was looking for the lens, it would be quickly covered with other books, faces would be drawn long and straight, and the seeker would pass without comment.

Meanwhile, the two remaining groups of front benchers were still fighting to control the original big lens. As the lens was passed from hand to hand, two of the tripod legs slipped out of their sockets clattered on to the floor, and it was at this point that Lloyd called the class to attention. Lloyd had wanted to know which students had not finished. Quickly, many of the frontbenchers made the required sketch from the textbook, purporting to show what they had seen,
labelled everything in pencil and were ready by the time Lloyd got to his front desk to "recapitulate" the work. The recapulation saw Lloyd make a diagram of the stem section on the board. He labelled its various parts A - B - C - D and asked students to describe their observations. At this point, the camera had caught many of the front benchers, not with their hands up ready to answer questions, but busy erasing their earlier flimsy sketches and replacing them with the large solid sketches similar to the one that Lloyd had drawn on the blackboard.

After Lloyd had watched the video tape segment he commented: "These fellows have let me down. I thought they were serious about their work." Subsequently, Lloyd had organized a more equitable system of monitoring class events. This new system consisted of first, gradually easing Lloyd's grip on assigned group members and their work and allowing students to re-organize themselves into groups that suited them, as long as these groups did not disrupt classroom work. Second, in monitoring student work, Lloyd attempted to balance his time between giving help to students who sought and needed help most, perusing around the whole class, and standing at the front desk more often in order to take a bird's eye view of the laboratory. It took Lloyd about 4 weeks to install all the elements of this modified system and he stuck to it up to the end of the research observation period.

It was perhaps, important that Lloyd, unlike Lydia and Dalia, had decided to tell his colleagues about the instructional changes he was making and the progress of these changes. These exchanges with his colleagues plus a more consistent effort to view tapes of his lessons outside seminar sessions, probably enabled Lloyd to come up with and investigate other aspects of his instructional strategy related to the problem of monitoring student work. Lloyd seemed to have had a clear concept of both the purpose of the instructional technique which he wanted to initiate and the processes of its implementation. At first, the effect of the implementation process had resulted in positive instructional change for the specific target group, but it had also introduced new problems to the rest of the class. However, in order to evolve a balanced system of monitoring and arrive at a proportionately effective technique for the whole class, had required Lloyd to make
two other changes which he had not originally perceived as related
to the monitoring of student work. In the first instance, strict
assignment of students into groups had to be eased. In the second
instance, Lloyd broadened his definition of monitoring from simply
believing that monitoring was most effective when Lloyd dealt
physically with individual students, to the appreciation that
monitoring by taking a bird’s eye view of the whole class, was
sometimes, equally effective.

Charity’s Instructional Changes

Charity had identified seven techniques, four of which she wanted to
initiate while the rest would undergo improvement. However, only
two techniques, namely, increasing the amount of teacher control
over student group work, and encouraging students to make their
own notes were implemented. Charity appeared to have selected the
most crucial techniques to change in her overall instructional
strategy. Two problems frequently discussed while viewing
Charity’s lesson episodes were the organization of student group
work during practical periods and dictating notes to students. Lloyd,
Dalia, Lydia and indeed, Charity herself, had found the conduct of
practical work by groups of students in Charity’s classes
exasperating. Lydia for instance, had once commented after
observing three groups of students doing the same experiment, “none
of the students in any of those groups started there. In that group
the students have been changing. Was that what you wanted? I don’t
see how it works.”

Charity had not set up formal student groups in the Form 1 research
class. She had left students to set up their own groups – more or
less- during each practical period. This was not an unusual practice
in this research project as both Dalia and Lydia did not have
formally mandated groups. What was interesting, however, was that
while in Lydia and Dalia’s classrooms students had managed to
consolidate their own group members, so that more or less the same
students worked together in almost all practicals, many of the
students in Charity’s class had failed to form similar bonds. This is
not to say that all students did not eventually have their groups.
There were about 15 students who formed three semi-permanent groups with two or three members as a core in each group. The other 25 students however, tended to attach themselves to various groups not only from one practical to another but also within a single practical session. I came to define this constantly moving group of 15–25 students as 'an idle mobile periphery' to characterize both their structure and their status in terms of responsibility for classroom work. These students were constantly moving idly and were peripheral, in structural terms, to a group that had a core, and to the learning processes which were being undertaken by the core group members.

By focusing on this idle mobile periphery, teachers had advised Charity to do something about the organization of group work. Teacher analyses of lessons in terms of trying to follow a student from one group to another, had revealed that even in the second term of first year (1983), Charity knew only a few names of her students. Lydia had attributed a great deal of what she called "lawlessness" during practicals, to this fact, because as she argued, students probably felt anonymous and were therefore, tempted to do whatever they wanted, knowing that the teacher would be unable to call them to task by name. Charity was therefore, advised to prescribe formal and mandated group membership. Initially, Charity tried to learn more of her students by names and during the weeks in which Charity worked consciously on this task, there was always an atmosphere of surprise among students whenever she called them by name. It seemed that after Charity had got about 15 faces and names tagged, there was realization by students that "she knows you". The tagging of students by name, was a positive and exciting phenomenon in the class while Charity worked on it, because for the first time, fewer numbers of students felt themselves anonymous during lessons.

Charity did not however, opt to take the second piece of advice from her colleagues regarding the formation of formal groups. Instead, she decided that whenever there was a practical, she would identify the leaders of a group. Charity did not want to discuss the issues regarding her new ideas on group formation, but at an informal
discussion with three members of staff in the biology and physics departments at Charity’s school, I gathered that in the science classes formal and permanent group formation was discouraged in the school for two main reasons. First, since the level of daily absence was high among students, permanent groups would always be difficult to work with, and re-grouping would have to be done in the case of absences. Second, teachers seemed to believe that since few students had much interest in science, especially at forms 2, 3 and 4, it would be unfair to condemn a student – particularly an interested student – to a permanent group where other members may not be motivated enough to do the work.

In Charity’s class there seemed to be another reason, perhaps even more poignant than these two. After all, the average level of absence in Charity’s research class was four students per lesson. Even though students who were usually absent tended to differ more or less each lesson, absence would not have severely disrupted permanent grouping. But there was a high level of lateness in Charity’s research class and other classes. During first form, this level was on the average, 9 students each lesson; and after the second term of second form it had dropped to about four. Charity had been consistently observed doing her lesson preparation in her head, using the ideal textbook requirements for allocating resources and prescribing personnel. If for instance, an experiment had four main tasks, Charity would prepare a lesson where students would have to work in fours, so that each student would have some task to do during the experiment, as was demanded by Charity. But not all experiments had four tasks, some had only 2, others 9 or 10 or even more. If Charity had set up permanent groups, she would have probably had to combine and devolve groups at each practical in order to cater for more or fewer tasks in various experimental situations. The best solution therefore, seemed to be to leave the groups open and subject to formation, composition and dissolution according to a particular practical at hand.

There was theoretically or practically nothing wrong with the strategy. In fact, the strategy, theoretically at least, embodies all the elements of individualized planning and implementation so often
recommended by teacher educators. However, in Charity’s case, there was one major problem. Charity often had very little time in which to undertake, herself, the actual preparation of learning resources such as: test tubes, microscopes, hand lenses, plants, leaves and any resources needed for experiments. She often had to rely on the assistance of an untrained laboratory technician who had little experience of classroom needs, had several other errands to perform, and had to work in two laboratories where several classes may be in session at the same time. On Mondays, Charity would begin by introducing her experimental lesson from her “prepared lesson in the mind”. But whenever it came to have the students break up into groups, Charity would discover that either equipment and resources were not available or more often, they would be insufficient for the kind of student grouping she had been talking about. Charity would then have to make ‘repairs’ to her earlier procedural directives concerning grouping, use of resources, or sometimes even the number of experiments to be carried out in any one particular lesson.

A situation had developed therefore, where a mental lesson planning strategy that had been set up to cater for three other problems, namely: student lateness, student absenteeism and the need for each student to undertake some task during practical work, seriously undermined the very instructional advantages the strategy had attempted to achieve. It is pointless to ask whether the situation would have been different had Charity set up permanent groups. It would appear that Charity had probably been correct to reject permanent groupings since some of the influences on her instructional strategy lay with the school’s management policies that dictated allocation of resources and the sharing of these resources by teachers. These were very difficult problems to work around. In the end, students grouping did not evolve along the lines that the other three teachers and myself had perceived it would.

**Encouraging Students to Make Their Own Notes**

The origin of advice to Charity about her student note-taking procedures was similar to that regarding grouping and name
tagging. Through viewing tapes, teachers had observed that Charity was not encouraging students to learn this necessary skill. Charity dictated notes directly while students copied them. Other teachers felt that students had to learn to take their own notes in order for them to develop the skill of narration, description and explanation through writing. At the beginning of the seminars, Charity had insisted that her students could not compose notes on their own, asserting, “they will write nonsense”. But her colleagues had maintained that students would not “automatically” write good notes, and that students had to learn to write good notes through constant practice. Charity had explained that she was worried about several points regarding student-made notes. For instance, she wanted to know:

1. How long would it take before students learned to take good notes?
2. How would she know when they had learned to write good notes?
3. Where would she get the time to teach the content and then give students time to write their own notes during the very limited time given to biology.
4. What should she do with students who failed to write good notes within a reasonable length of time?
5. What was a reasonable amount of time in which to decide that students had or had not learned to make their own notes?
6. How would she be sure that students had composed the notes themselves and had not just copied them from a textbook?

There was no shortage of answers to all these questions from Charity's colleagues. Everything was made to appear very simple, after all, the other three teachers had anecdotal examples galore, collected over their long teaching experiences. Teachers emphasized that given the chance, students can and do learn to take excellent lesson notes. Charity finally, but somewhat hesitantly, agreed that she would get her students to learn to make their own notes. During the third term of first form in 1983, she implemented the new technique. The instructional initiative consisted of three main elements. First, during lecturing, Charity would put the main
headings of concepts on the blackboard and consecutively add the sub-concepts that followed. Second, she would allow students to write their notes on the concepts and subconcepts and on whatever else they thought they needed. Charity would make frequent pauses designed to give students plenty of time for note writing. Third, Charity had evolved a system where she would give a list of short questions either as she lectured or more often, at the end of each lecture block. These questions, designed to consolidate and extend classroom lecture notes, would be written at the back of notebooks, and students were expected to answer them as homework or assignment after each lesson.

By the end of third term of 1983, Charity had almost ceased dictating any type of notes to students except for questions. However, at the beginning of 1984, Charity was observed to have become visibly uncomfortable with the student notes-writing system. Asked whether or not the new system had worked well, Charity had explained that her Form 1 class, although not with the lowest scores in biology in the school, had not performed as well as several other streams. The biology test that had been given to all 6 streams at the end of 1983 had been a recall test and Charity's students had not done well.

During the following seminar, teachers discussed Charity's concern, namely, that because she had given more of the teaching time to students in order for them to make notes, she had been unable to cover properly, the same amount of detail in the assigned topics as that covered by students in the other five streams taught by other teachers. Charity had then stated that she wanted to reduce the time devoted to student note writing. The other teachers offered encouragement explaining that persistence was the key to success. Lloyd offered to bring, and brought to the next seminar, a series of notebooks kept by one of his students from first to fourth form. He maintained that looking at these notes, would enable Charity to "see" that every student started by taking notes rather poorly but that with practice, improvement was inevitable. But Charity was not really convinced that her own students would ultimately
succeed and she kept on insisting that she had to cut down on the time for note writing since she had to cover the syllabus.

In actual fact, the main problem to Charity's new instructional technique did not lie in not covering the syllabus, but rather, in the fact that Charity's notes-taking system which she had so carefully implemented, lacked two necessary elements, namely: teacher's constant checkup on the accuracy of student made notes, particularly their definitions of technical terms many of which formed the bulk of the examination questions; and marking of student notes by the teacher, at least, at the beginning of student attempts. It was not a practice in Charity's school to mark student notes regularly. After all, if the teacher had dictated the notes, they were sure to be correct. Charity had not realized that she could not continue with this system as long as she required students to take their own notes. Therefore, the only student record of what they had learned consisted of what they had understood, which unfortunately, was not always quite accurate.

During the weeks that followed the above seminar, Charity had maintained her student notes-writing system, but she could still not seriously correct student notes. Two teachers had been transferred from the biology department, creating a heavier teaching load for Charity consisting of 32 periods a week. The last straw on Charity's increasingly strained program, came a week later, when the results for the annual public 'O' level examinations results for 1983 were returned to schools. During assembly throughout that week, the school head had taken all teachers to task, claiming that they were not working hard enough. Singling out biology (and three other subjects) as one of the subjects performed poorly by students, the head had commented, "in a simple subject like biology, everyone ought to pass." The head had then ordered all teachers to GIVE notes so that students would be able to revise from accurate class work after school.

Charity had immediately reverted to her old system of dictating notes. However she did not abandon entirely the new system she had installed. She continued to give more time to write out
experimental work and gave more and more questions to be done as assignments. Charity also realized that marking student notes was important and she instituted a strategy of marking books and monitoring the completion of all assignments during class time. But several forces later combined to make this arrangement almost counter-productive. For instance, on several occasions during assembly, teachers were denigrated by the school head for apparently, not giving students "good notes". This public censorship made it very difficult for teachers to control discipline in class. More significantly, some students began to pay less attention to their out-of-class assignments since they expected teachers to give them notes. The more pressure the head put on teachers to perform better and work harder, the less effort Charity put into ascertaining that students actually understood their own responsibilities in the learning process. Charity, therefore, discovered that more and more assignments were ignored or incomplete. This led to more public counselling and monitoring of student work during class time, which in turn, reduced substantially the time for teaching and learning. In the end, when I asked Charity why she had reverted to dictating notes she said:

"My class would have been the only one with nothing to read and revise for the examinations. I was the only one not dictating notes. Moreover, if you look at the notes students have copied in dictation, they have many mistakes. Imagine what would happen if all the notes were made by them."

Asked whether or not giving and dictating notes would, alone, improve student achievement, since it did not seem to have had much effect in the last 5 years in the school during which it had been practiced, Charity replied: "I don't believe it will improve passing. But then that's not the point. The point is that I don't want anyone to say I did not give notes."

Charity had of course, not very systematically thought through the implementation of her new instructional techniques, but she was initially prepared to make changes as new insights arose. However, what ultimately led her to abandon the new changes was not simply the school head's directive on giving notes, but also the isolation
she felt in implementing the innovation alone in the school. This isolation was particularly important for purposes of accountability. Her colleagues and advisers on change were working in different schools, and Charity could not call upon them to defend her instructional strategy in her working environment.

**Stability of Instructional Change**

Stability can be defined at two levels, namely, stability of implemented instructional change across classrooms taught by a particular teacher and stability within the research class, vertically through forms 1 to 3. In the first instance, Dalia and Charity's examples have shown that the very process of implementation of change is itself fraught with problems. Reflecting on the totality of the experience, change in individual classrooms did not appear to become very stable unless the teacher had beforehand, isolated some school-wide factors that were likely to affect classroom changes. Taking into account such factors and setting up mechanisms in order to reduce the impact of such factors on individual teacher efforts also appeared to minimize conflict between individual classroom instructional changes and school-wide attitudes, beliefs and prescribed practices. But Charity's case demonstrated that even where an implemented change was 'dropped' to revert to the original technique, important remnants of the new instructional technique were incorporated into the old system, so that stability of some elements of the new changes was observed up to the end of the project, even though the major instructional change had been abandoned.

In Lloyd's case, it was clear that attitudes, beliefs and practices in the school presented little or no problem to the implementation of changes that Lloyd instituted. In fact, the major initial obstacle to the success of the implemented instructional change was due to Lloyd's decision to "go all the way" with an instructional change that he thought concerned only a few students in the class and not the whole class. What finally evolved, after several trials and correctives, was a more balanced system of monitoring the practical work of students which remained operative up to the end
of this research project. In Lydia's case, since all the implemented techniques were, to a large extent, already part of the overall instructional strategy, school-wide policies and practices did not appear to have presented any problems during implementation. Lydia continued to use the refined techniques up to the end of the observation period.

On the second aspect of stability, Lloyd was the only teacher consistently observed teaching classes at levels different from the research class. He was observed teaching at forms 3, 4 and 6 during 1984. In form 1, 2 and 3, Lloyd appeared to use more or less the same instructional strategy that he had been observed using in the research class, which was then at Form 2 level. It was observed that Lloyd had transferred his new monitoring technique in the conduct of practical across form levels. In forms 4 and 6, Lloyd's instructional strategy appeared to be different in the sense that students seemed to have more opportunity to discuss concepts and challenge Lloyd on various issues. But even here, Lloyd seemed easily to maintain his usual authority, allowing alternative interpretations of points of contention to emerge but only as long as they were either correct or reasonable alternatives. In any case, Lloyd always had the last word.

In general however, it would have been exceptional in this study if the real new changes had all been sustained over much longer periods than those indicated in the cases of Charity and Dalila. There appears to be evidence that the present structural and social organization of schools make it extremely difficult for teachers to sustain change. For instance, Ireland and Russell (1978) during the Ottawa Valley Teaching Project, worked with a group of teachers who were interested in "affective and higher-order cognitive objectives and used reflection-in-action strategies to discuss their work and techniques of implementing change. Similarly, Elliott (1977) worked with a group of 40 teachers in the Ford Teaching Project in England (1973-1974) all of whom had expressed some commitment to attempt to implement the "inquiry/discovery" teaching approach in their classrooms. Russell (1983) reports that in both groups, virtually all participants seemed to value the
increased self-awareness they achieved, and that teachers found much in common as they talked to each other about what they saw in their own practices. However, only a small fraction was able to sustain major modifications in their teaching. Russell concludes that, "self-monitoring is difficult to initiate and continue within the contexts of our present schools." Collaboration among teachers within the same school would therefore, seem to be a prerequisite if major modifications in teaching are to be sustained.
Chapter 5

TEACHERS AS RESEARCHERS

A good education, be that of pupils at school or university or even for older teachers like ourselves, does not come easily or cheaply. Lydia (1985)

Teachers Meet Colleagues as Researchers

The four teachers who participated in the research project undertook to study various aspects of the Kenya educational system during the second year of the project (October 1983 - October 1984). This was not a research project in the strict sense. The activity simply consisted of gathering and discussing information on areas concerning dynamics of the educational system. Throughout the year, individual teachers and myself discussed what teachers were finding out. During a seminar in late 1984, teachers agreed that their findings would be presented to a larger meeting of their colleagues for further discussion.

The meeting which was held on Saturday, May 18, 1985 was attended by 18 male and 14 female teachers from 19 different schools from Nairobi, Kiambu, Thika, Meru and Nakuru. Only one teacher, a man, had had 1 year of teaching experience. Of the remaining 31 teachers, 11 had taught between 2-5 years, and 21 between 6-14 years, respectively. Of this latter group, 10 teachers had taught at least 8 years. Half of the teachers present were teaching at all levels of secondary school and in this group, there was one school head and 14 heads of departments of biology.

Because of the nature of issues that were to be discussed, teachers had purposely decided not to invite personnel from the Ministry of
Education and its various organs. Teachers had feared that the presence of "official" personnel would influence the quality of self-expression of individual opinion among participants. Teachers were aware that the very nature of the duties that are performed by these officers, restricted their discussion of some issues and often demanded that those who performed such duties defend their "official" actions.

As it turned out, teacher fears had been justified. For instance, they had invited an officer who had previously been a participant in the research project but who now worked for the Kenya National Examination Council. During the seminar many issues concerning examinations were raised and discussed. But teachers were disappointed when the officer could not answer many of their questions which involved his job, leaving some teacher with the impression that he had changed from the ordinary teacher some of them knew, to an officer "with secrets to protect".

My introductory remarks clarified three issues, namely, who was holding the meeting; the purpose of the meeting; and the expected role of the participants. Teachers in the research project had pointed out earlier that in a meeting of this nature, introductions were very important, particularly, when it came to establishing the legitimacy of each participant present. One could almost see the sense of excitement as teachers craned to see teachers from various schools. I explained the purpose of the meeting and introduced the four teachers who had participated in the research and gave a brief sketch of the project. I emphasized that teachers and their guests were in the meeting to exchange ideas issues on which teachers had been gathering data for the past 2 years.

Dalia made the first presentation on the topic "The Effects of Having Long-term Classroom Observers". Dalia gave a personal testimony of her own feelings and reactions to the "ever present observers" in her classroom during the past 2.5 years of her teaching experience. She described how her feelings and reactions had undergone four stages. First, she had tried to please the observers, but she had become very tired because of the pressure
which this had put on her daily. Second, she had become fed up with the observers so that she had decided not to care whether they were there or not. Third, she had started caring again and had attempted to improve her instructional strategies. Finally, she had settled down to doing what she thought was best for her class regardless of the presence of observers. Dalia described her initial reaction to observer presence as one characterized by a vacillation between "preparing" herself for the observer, and letting the observer "take me as she found me." She stressed that through the period of observation, she had reached three conclusions.

1. No teacher or researcher should expect teaching to be normal when there are observers or gadgets such as tape and video recorders, because regardless of how long the observers or gadgets stay in the classroom, they cannot become part of the class, from the observed teacher's perspective.

2. No improvement in teaching can be initiated until the teacher has gone through the vacillation period on one hand, trying to do what the observers expected, and on the other hand, doing what the teacher thinks is correct regardless of the observer expectations.

3. It takes students in the observed class even longer than the teacher to get used to the presence of observers and gadgets.

Dalia described her student reactions to long-term classroom observers and video taping this way:

"At first they [students] were not terribly worried. They had seen other observers in other classes in primary school. But their actions in class were not normal. They did not behave normally. Their general response was negative. They were afraid of putting up hands, just in case they said the wrong thing. You see, at first they thought the observer was evaluating me. I had forgotten to introduce the observers properly. After the observers came a third time, they really started wondering why these persons were coming to my classes. They were frightened and they panicked. They were afraid to ask me just in case I was the one in trouble. The breakthrough came one time after a researcher had observed a lesson and we stood outside and had a humorous discussion for about 20 minutes. The students were watching us laugh. They figured all cannot be bad if we were laughing. After that they asked me why the observers were coming and why to their class. Then I explained. Later on the students got instruments to fill in and they found they liked these instruments and this eased their
minds. Much more important we arranged so that the students could see some of the video tapes. This first happened one Saturday morning, and they talked about the tape, what they had seen, and how they appeared for more than two weeks afterwards. After the video, they were really interested. They got more or less used to but were still fascinated by the equipment. They even improved and became very conscientious and I could sometimes see that they liked to act for the camera."

As to Dalia's own reactions to the long-term observation and video taping she said:

"Well it really demanded a lot. You had to be well prepared all the time. You had to project an image of a good teacher. But the video taping was something else. At first, I was worried. I did not know how I was going to look. I was not sure who else was going to see my tape. Therefore, I think I always taught badly on video tape until I saw myself. When we saw the video tapes - fortunately we started with other teachers - so I was not the first, then I saw that no one was really trying to find faults with any particular teacher. It was just learning. In education we make so many mistakes because we are not researching enough. After you see yourself on video and you count your errors - then you decide to do something about it."

Dalia was bombarded with questions regarding the feelings she had expressed. Teachers wanted to know particularly, whether or not Dalia thought that the observers tended to create "disturbance" by over-vigilant rotating of cameras in an attempt to capture scenes from the whole class. Teachers also wanted to know whether or not other teachers in seminars, did not tend to give unfair criticisms, in view of the different school abilities to provide sufficient teaching-learning resources. But Dalia, calling on support from her seminar co-participants, emphasized the fact that even though all these problems had been there, they had not been major. Dalia stated that if she had to go through the same experience again, she would pay more attention and devote more time to the seminar discussion and interviews with the researchers since they were the most useful aspects of the research. Dalia pointed out that classroom observation and viewing and discussion of video tapes took a lot of time so that as a teacher she sacrificed so much of her time to the project. Dalia pointed out that there was need to work out a system whereby if a teacher was participating in this sort of research, there would be some official recognition of the teacher
role in the school so that the teacher does not become overburdened with work and thus, becomes disillusioned with the research.

Complementing Dalia's description of the general feelings teachers had regarding the presence of longterm observers in the classroom, Charity had stated:

"When you work every day in your own school 5 or 6 years, you only talk to teachers in your school. When there is something wrong in the school, you all tend to believe that it is only in your school. And when you hear something good about another school, you imagine that only good things exist there. What I learned through discussion with teachers from other schools was real. It was not the rumours. I found out that all schools have problems - many of them the same problems. Also that all schools have something they are doing very well. The difference is the way they do it-the way they choose. I think this is what really makes a difference."

In the second presentation Lydia talked of an issue of wider concern in the total educational system namely, "Do Biology Public Examinations Match the Content of Classroom Teaching?" Lydia introduced her presentation by telling teachers that she had been fascinated by this issue by being involved in three different experiences. First, marking of public examinations had introduced her to differing points of view on the issue by markers of examinations. Second, participating in research had enabled her to take part in numerous discussions on interpreting the syllabus, teaching for public examinations, as well as problems of teaching at the "right depth". Third, matching her classroom teaching to some external examination had always presented a great challenge. After discussing the problem from these three points of view, and stating the advantages and disadvantages of each position, Lydia said:

"The issue is controversial. Because if you say, I am going to teach as I wish, with no regard to the existence of examinations, then I think you will have a problem. On the other hand, the examinations, I think, are not set on what is actually taught in the classroom but on what is in the syllabus. Generally, I would say that the examination should try to match classroom teaching but there are two main problems. First, who actually knows what has been taught? And second, what is the proper matching?"
Lydia explained that, by and large, public examination questions reflected what was in the syllabus - "topicwise". But it was not uncommon to find public examination questions which tested what was not expected either at the depth of teaching at the school level from the reality of the physical circumstances of many schools. Lydia quoted examples of public examinations where sometimes questions requiring university level knowledge had been set for A level candidates. Lydia's presentation was followed by a long and lively discussion where the gist of teacher opinions consisted of the following points:

1. **There was little co-ordination between curriculum developers, subject inspectors - who should assess the depth at which various topics are taught and what has actually been covered during teaching.**

2. **Many teachers, in interpreting the syllabus, only look at the content being unaware that public examinations are more concerned with the coverage of objectives rather than individual topics.**

3. **Many teachers had difficulty dealing with social objectives while teaching subjects such as biology, chemistry and physics. The curriculum developers should spell out more clearly how such objectives can be handled and operationized in the classroom.**

In summarizing the discussion Lydia emphasized: "an examination should not be an exact match to classroom teaching. The examination should be beyond teaching. Students should be able to use their heads to answer a question even if something was not specifically taught." Asked to explain in what way participation in research had helped her to improve her teaching, Lydia had stated:

> At first, I thought I knew a lot about teaching and education in general, since I am lucky to be working in a good school. I thought that since the students have been passing their examinations very well, that we were educating them properly in everything. But through interviews and discussion, I came to realize that we all have a long way to go, in all schools. You see, in classes, we are not really that efficient. Learning and teaching could be better. We assume that when students are sitting in a biology lab, that they are only learning biology. By looking at the video tapes I was able to see that my students, just as in other schools, were learning and doing things that I had not intended. I came to realize that many of the discipline problems in class are the result of what students have learned about a teacher’s behaviour. No
teacher is able to notice this sort of thing until other teachers point it out to you. But it is also important to have a researcher who will help all teachers to see various points of view. I think as teachers we tend to see only what we think is good or bad. We do not look in between. And that is the real source of our problems.

Lloyd's presentation was on the topic: Where Should Emphasis be in Training Biology Teachers: Experiences from Research and Teaching. Lloyd began the discussion by asserting that since almost everyone in society felt himself competent to comment on and criticize teachers, it had come to sound as if everyone could play the role of a good teacher. Lloyd pointed out that knowledge of specific subject content was only part of a teacher's role, and that the other aspect of a teacher's role consisted of a social dimension, dictating a coherent pattern of behaviour. Each teacher had both an ascribed and an achieved role. The former involved duties such as; class-teacher, a games teacher, a deputy head of school; while the latter depended more on a teacher's ascribed status, but without considering where and how the teacher worked at his other roles. Lloyd argued that in addition to the ascribed roles, the teacher must also develop definitions of himself with regard to his job and status: "what does he think of himself? Is he a teacher only? Or is he also a member of society, a member of local pub, a member of a football club and so on?"

Lloyd pointed out that participating in the seminar discussion had helped him to begin to constantly examine such issues and to see in what ways his answers were likely to affect the way he taught. Lloyd said that while over the years, teachers had come to gauge their expectations of other teachers by more realistic standards, society in general, had evolved expectations that were far from reality. Thus a teacher was expected to be considerate, disciplined and orderly. He was expected not to fight in public, not to drink and not to complain about poor pay. There was need however, to look at the teacher roles by asking whether or not there was something special about a teacher's work which dictated that he should reach such high levels of morality which other ordinary persons in society are not expected to reach. Emphasizing the need for teachers to
discuss such issues, Lloyd asserted, "many of us don't know who we are any more."

Addressing himself to the nature of teacher training, Lloyd wondered whether, in view of the various expectations for teachers as very special people, society was training teachers to meet these high expectations. Lloyd asserted that it had become obvious that recent graduates "were packed up" with knowledge but lacked professional ethics: "they regard teaching just like digging. They can walk into a school with a checkered cap or a skewed scarf on the head, a trouser with the bottom hems trailing 40 inches below the ankles, no jacket, front buttons on the shirt open to the waist, chewing miraa or cigarettes, and expect to teach properly academics and morality." Lloyd asserted that the teacher training colleges were doing a very good job in the "knowledge sector", but that they were not doing enough in preparing teachers in the important area of professional ethics. Several issues were raised during discussion regarding teacher training, certification, promotion and professional growth after certification with emphasis on the following points.

1. There was need to give the teacher trainee sufficient exposure to real classroom life before he went out for teaching practice and final evaluation in order to obtain certification.

2. A single teaching practice was not sufficient to help the trainee to appreciate the complexities of different classrooms and students in different school situations.

3. Teaching practice placed too much emphasis on policing trainees, assessing and awarding grades, passing an examination, and identifying weaknesses but rarely helped him to improve and grow and consolidate his strengths.

4. The need for, and meaning of the probation period for a newly qualified teacher was no longer clear. Similarly, it was neither clear if the head of school still wrote probation letters to the Inspectorate regarding the new teachers' performance, nor if inspectors still took part in the training and certification of teachers.

5. The teaching profession was still plagued by the twin problems of recruiting entrants from the bottom of the achievement ladder; and
providing a stepping stone to other jobs. This was because secondary school teaching did not seem to require competent professionals since the pay was low, and the prospects for promotion and upgrading were almost non-existent.

6. The social expectations for teachers were superhuman. While the teacher should be a model, with only don'ts as the code behaviour, he was publicly despised due to the meagre income accruing to his job.

7. Society should not expect good teaching simply because a trainee has got a first class certificate from college. For a teacher to become good and remain so, demanded systematic professional help and rewards commensurate to the effort and adaptation that teachers have to put in whenever the educational system and school curriculums change.

The last presentation on the topic: "The Contribution of Parents and Community to Poor Learning by Pupils", was given by Charity. Charity's basic contention was that many parents had not yet realized that for the majority of primary school children, and day secondary school students, useful classroom learning should be supported by proper social learning at home. Charity pointed out that many parents did not take seriously their role as teachers once the children start school. She said that the pressure on mothers to put in standard working hours in the urban sector, meant that very young children were left in the hands of young or inept housegirls, who had too many duties in the house to pay attention to the child. Where the mother did not work, the family tended to have many children who kept the mother too busy and exhausted to educate them properly. As a result, diets were poor, money was always scarce and living quarters crowded so that fighting between parents and among children was frequent.

Charity explained that a sizeable proportion of secondary school students attending day schools in Nairobi either lived in single parent families or were staying with relatives because their parents were in the rural areas. Many of these students, especially girls, were overworked at weekends; they often woke up extremely early in the morning to make breakfast for the family; and after riding on very crowded public service vehicles, arrived at school harassed, tired and in no mood to do serious academic learning. Charity stated that many students were too busy doing home chores
to complete assignments at home and that their parents, relatives and guardians neither bothered to remind students of the need to complete homework nor motivated them to do any reading. The same students, Charity added, concentrated very little in class, were subject to constant disciplinary punishments in school for lateness and inattentiveness in class and submission of incomplete assignments. Charity stated that students in day urban secondary schools often suffered a triple disadvantage due to the location of both their homes and the school.

"Many low income homes within the city radius are overcrowded, with few amenities, poor parental support and are often situated in areas where the brewing of illicit drinks, and other illegal or anti-social activities are in general practice. It is often the case that a student living under these conditions will go to a school which is itself sandwiched between busy highways with the honking of taxi-horns as a perpetual disruption. The same school may be near 24 hours-open cinema houses, kiosks or discos to which students are tempted to sneak during class time. These schools in 'no-man's land' to which these students go have therefore, no tangible community support. The surrounding community to the school is often too diffuse and mobile to be bothered about school. The parents are often too busy making a living, to pay attention to requests initiated by school for support, be it moral or financial."

Charity stated that participating in the seminars had helped her to see different ways of interpreting these factors and conditions.

"We were always encouraged to see the other side of the coin. And I think that is where teacher discussion really helps. Before I took part in the seminars, I knew about most of these factors and conditions. I always thought that the people caught up in them were mostly responsible. Now I can see that there are many other factors involved."

The discussion that followed reiterated the same problems emphasizing five points.

1. The majority of parents - not just the poor, the rural or those who have had no formal education, had not realized that not everything can be taught in school, and that parents needed to keep in touch with schools in order to find out what they can teach their secondary school children.
2. A large proportion of parents in the urban areas were overburdening their teenage children with too much housework leaving them very little time to study and complete school assignments. However, some parents, especially the well-to-do, were giving too much play time to their children, treating them like breakable objects, instead of teaching them to do some chores and the value of manual work.

3. A small proportion of parents had a genuine desire to help their children with school work or school related activities but they lacked the knowledge. The P.T.A. meetings had increasingly become political meetings, often concentrating on only how to collect *Harambee* funds instead of seriously discussing classroom work and how such work can be improved through community and parental support.

4. Teachers working in urban schools were subject to the same temptations of neglecting their duties just like other civil servants. Several factors were often in play. For instance, decent housing was difficult to obtain. Yet the allowances given were too small. Under these circumstances the only way a teacher could afford a decent house, in a reasonable neighbourhood was to run a business during teaching hours.

5. The recent trend to build student hostels and dormitories for schools in urban areas was an extremely useful step in overcoming some of these problems. But this step by itself would not raise the standard of academic achievement in urban schools unless other problems of urban schools, such as neglected management, teacher welfare, school facilities, learning resources, and urban planning, were simultaneously considered.

**Teacher Development**

A summary of these four presentations has been documented for three main purposes. First, each of these presentations dealt with an issue of informal research which each of the four teachers had chosen to study during the second year of the project. These were areas the teachers identified themselves. The purpose was not to teach or train teachers to do research. Rather, the purpose was to get teachers to pursue a problem or an issue consistently throughout the project so that they could see its broader implication in their own work and the wider educational system. And as has been shown, each of the issues investigated and discussed at the seminar was of great interest to all teachers. And the fact that none of the problems raised on each of the issue was resolved, suggests that all
these issues continue to be of great interest to school personnel in general.

Second, the four presentations throw some light on the confidence with which teachers in the project had come to present and argue their points of view. To me it was a source of immense satisfaction to see how the research project teachers, when confronted with polarized questions from other teachers, attempted to evolve a balanced point of view. This was of course, something we had painstakingly strived to achieve during interviews and seminar discussions. It appeared to me that the ability of teachers to feel and act confidently brings with it not only the capacity to synthesize information from different sources and to weigh its merits and demerits, but also the ability to do what Lloyd once described as "reflecting at both ends of the scale". This realistic view of issues, problems, solutions, and strategies characterized the research teacher presentations and discussions. It is quite true that its roots were obviously, in the minds of teachers before the start of the research project, but as the teachers themselves pointed out, the interviews, the discussions and interactions with other teachers contributed to its growth and greater expression.

With regard to teachers who attended the meeting but who had not participated in the research project, there was initially "silence" as they sized up each other. Fortunately, this happened during most of my own presentation of the introductory remarks. But once the ball got rolling, the problem was really one of time. Teachers literally poured out questions, criticisms, comments, explanations, defence and demands. But the meeting was not always smooth. For instance, during the discussion that followed Charity's presentation on Parents Contribution to Poor Learning, a male teacher had pointed out that mothers with large families tended to be cruel to their children. A female teacher disagreed vehemently. A second male teacher drew the meeting's attention to an article that had appeared in a local newspaper the previous day entitled Women Criminals. Several female teachers wanted to talk at the same time, explaining that these criminal activities were exaggerated and that women became criminals only after mistreatment by men. A male teacher
shouted that young men mistreated their wives as a result of men's earlier mistreatment by their mothers. A female teacher disagreed, stating that in her experience, mothers mistreated their daughters more than their sons and in fact often spoiled their sons. Some female teachers insisted that it was fathers who always abandoned their children who then became parking boys loitering the streets. The male teachers pointed out that it was mothers who failed to educate their sons as "fathers" in the first instance.

There were these minor confrontations and emotional outbursts, and defenses of the sexes, jobs, roles and status. The Ministry of Education and its various organs also came under attack on many points of our discussion. And since these organs were not represented, they provided an easy target for the pent up feelings of teachers. But what all these various degrees of emotional and intellectual commentaries underscored was the need to have frequent meetings of this nature to enable teachers to get a few things off their chests. The whole record of discussions during seminars, right from the beginning of research project to this larger meeting, clearly showed that teachers need to learn first, to manage their emotional feelings of professional vulnerability and defensiveness in order to use their wealth of intellectual and practical experience for constructive intellectual discussion, reflection and instructional change.

Teachers suggested that there was need to set up communication channels between various organs of the Ministry of Education and teachers in order to improve the teaching-learning process. Teachers were generally unhappy with present methods of communication by circulars, some of which they said rarely, reached them. Teachers said that they wanted to have a say in curriculum development, examination setting, teacher training and the certification of teachers. They also wanted the broader society to take a more realistic view of both the possible and potential work that schools and teachers can do in educating children as well as what parents should do in order to take a more active role in educating their children in their own homes.
Many teachers stated that they were aware that they were not doing the job of teaching well enough and to their satisfaction. While many teachers were willing at first, to quote a catalogue of "external" factors that prevented them from performing their jobs to their maximum best, many later admitted that they themselves and other people such as researchers, the university teachers, the ministry officials, the parents and indeed the schools were not doing as a good a job as could be expected as a result of "internal" or personal factors. It became clear that many teachers detested pontification from above, some felt that they and their schools had become guinea pigs, but the majority were genuinely looking for help in the field. The main question that was left unanswered at the end of the seminar was: how do we help the teacher without robbing him of his experience and status?

A Look to the Future

Many of the teachers in the seminar and in the four schools who participated in the research were interested in improving their work. Practicing teachers comprise a large educational community which should increasingly make a greater input into educational research. The stage should ultimately be reached where teacher involvement in classroom and school research should be the accepted norm. The major problem, therefore, is to find suitable strategies that teachers can use to take on new tasks beyond their already over crowded schedules. While the intellectual benefits such as: developing new insights about practice, merging theory into practice, sharing an "internal bank of data and classroom practices", increasing teaching effectiveness, and accessibility to collegial discussion and interaction; all of which teachers are likely to gain from involvement in research are undisputed, there is considerable argument with regard to the wider issues of professional growth and financial compensation. As Shallaway et al. (1978) have noted, financial compensation is necessary, but "compensation must also come in the form of increased opportunities and outlets for the professional experience and knowledge gained as a result." Plans of strategies to ensure that professional growth does not terminate at the end of a teacher collaboration and involvement in a particular
research project, should be part of the initial teacher considerations for involvement.

Through this research and from general experience, it is apparent that a single formula will not work for all schools and teachers for several reasons. Looking at only the four schools in this research, it was evident that teachers saw the needed improvement in their instructional techniques as concerning different factors, although, for all of them the ultimate goal was to get 100% achievement for all of their students. For instance, Lydia at National stated that a major improvement needed in her school was to synchronize the interpretation of the syllabus across class levels. She was satisfied with the general management of the school and student discipline. Lydia was quite convinced that, at least, in biology, if teachers taught at a reasonably synchronized level in all streams, the grades would improve uniformly among students in the school.

At Provincial, Lloyd believed that improvement was needed by way of implementing a reduction in the amount of duties for some teachers in order to free these teachers to do more remedial work with individual students. Discipline and general school management was already good, although Lloyd felt that there should be some improvements in overall school organisation to enable more flexibility for teachers and students.

At District, Dalia saw improvement as needed in areas such as coordination of work by teachers, building teacher commitment to the school and to their work, strengthening the administration through proper duty delegation, and carrying out remedial work with students. Generally, Dalia was satisfied with student discipline and believed that a general improvement in school management would improve academic achievement which would, in turn, be a stimulant to better discipline.

At Urbana, Charity felt that school management had to be improved in order to tackle the major problems of student discipline and teacher commitment to their work. Charity believed that without first solving these three problems, there would be little
Improvement in student achievement. It is obvious then that if the suggestions of the four teachers were to be considered, each of the four schools would have to do different things in order to improve just one area, academic achievement.

But underlying all these different 'problems' and as an initial technique in order to find out the universality of these problems, is the fundamental requirement for discussion in schools. As a general strategy, teachers suggested that all school personnel should become more open to discussion about working out solutions to their problems than is currently the case. Experience from these four different schools clearly illustrated that, while there was room for meetings that bring together people from different schools or even different institutions, such meetings were unlikely to be very useful when it came to discussions, solving problems and devising ways to implement changes and innovations within particular schools. We saw earlier how Charity's implementation of an innovation suggested to her by teachers from other schools was plagued by problems because its implementation was done in isolation of her school's basic beliefs and practices - beliefs and practices that did not exist in the schools from which the teachers who had suggested the changes worked. Furthermore, professional teacher development should as much as possible avoid using strategies of 'mass mobilization' that attempt to "convert" all teachers to either use of a particular teaching methodology in a new syllabus or adoption of a research finding. As has earlier been discussed, mass conversion training techniques do not appear to work probably because as Fenstermacher (1978) has pointed out, they overlook the beliefs that a teacher already holds with respect to an aspect of teaching practice to which new methods or research findings are relevant. Russell (1983) points out that given an alternative, people would rather undergo transformation than conversion so that personal reflection on one's own professional actions, appears to have considerable significance within approaches that attempt to foster transformation. Ultimately, each school should 'rear' its own group of promoters of change. Each school should create an organizational infrastructure in order to identify the structural and social-cultural beliefs pertaining to
various practices so that when different subject departments seek
to implement changes - instructional, financial, resource sharing,
linguistic, organizational and structural factors - the whole school
is ready to adapt within the necessary framework as perceived by a
significant proportion of school personnel.

We identified the following factors as prerequisites for a system
that promotes innovation and change within individual schools:

1. Every school should begin to consider its own personnel, including
   students and some non-teaching personnel as the 'right' people to
   assist in the identification and solution of problems. The hidden talent
   and potentialities of all school personnel which are at present ignored,
in preference to those possessed by 'outsiders' must be sought,
harnessed and used.

2. Every school should begin to view its potentialities in academic
   achievement as limited and curtailed not so much by the amount of
   human intellect possessed by its students and teachers but by the
   ideology, beliefs, and practices of its administrators, managers and
   teachers, in relationship to the nature of the teaching-learning
   process, and the traditions of the school, both of which are the result of
   social conditions existing in particular schools at particular points in
time.

3. Every school should begin to view the potentialities of its students in
   academic achievement as amenable to expansion through
   pedagogical and management considerations. Improvement in
   student academic performance must be tackled through an
   integration of knowledge on organization and use of time,
   understanding the social purposes of education and schools and the
   value of positive attitudes and beliefs in the processes of changing
   personnel and institutional behaviour.

4. Every school must begin to view itself as a learning place not just for
   students but for all who live and work in it as well as for all who come
   in contact with it. While the learning processes in classrooms would
   continue to be dependent on pedagogical innovations initiated by
   individual teachers, learning throughout the school should be
   increasingly characterized by a very strong dimension of analysis of
   purposes, practices and the continual evolution and conceptualization
   of alternative ways of doing things.

5. Every school should set up "outside" of classroom instruction, a
   learning mechanism that: (a) identifies the specific needs, aspirations
and achievement of various groups in the school; (b) designs techniques for strengthening effective strategies in all spheres of school life; (c) designs techniques for the reward of small daily victories in all areas of school life, and strengthens the link of these victories to the ultimate purpose of education; (d) undertakes to continually search for concrete solutions to old and new problems; (e) devises a system of harnessing the potential of all school personnel and organizes the flow of information within the school; (f) designs a system of harnessing immediate environmental resources and talents which are untapped in both the academic and social development sectors; and, (g) devises a system that eliminates language and communication barriers within and outside the school, reduces social deprivation and renders each school open to new experiences.

To date, the so called "good" schools already possess many of the elements listed above. However, the potential of these elements to benefit all school personnel and lead to total growth, academically, professionally and socially, by all those who live, study and work in such schools is curtailed by at least, three factors:

1. The elements are couched in a language and implemented through practices that deliberately indicate that they are for the sole purpose of controlling or containing students and teachers.

2. The elements are implemented within an infrastructural and management framework that emphasizes the fact that the quality of knowledge is unidirectional and is linked to status.

3. The elements are operationized within situations that separate the processes of teaching from those of learning and thus emphasize and reward only limited forms of learning.

These three points imply that to date, no school is already above learning. The 'good' school which has already achieved high performance on public examinations, has as much learning to do as the poorest achieving school. Incorporating discussion in individual schools or among a group of schools will entail its own problems. For instance, teachers who participated in this research and those who participated in the last 2 seminars suggested that something had to be "mandated" so as to bring about communication within and among schools. Associations of teachers were suggested, a journal for teachers was recommended, a newsletter of innovative teaching, seminars, meeting, fairs, and exhibitions were identified
as possible mechanisms. None of these mechanisms or activities falls outside the 5 pre-requisite factors that I have outlined above. What is required is to rethink the whole purpose of communication because the unanswered question remained: who will begin the process of change?

And here might lie the opportunity for teacher training to rethink their own strategies and methodologies. Kaplan (1976) in a rebuttal to half-hearted attempts to equate teacher participation in research as equivalent to change, has cautioned that "without the tools to question our own behaviour, there is little hope for improvement" (p. 68). The question which arises is: are teacher education programs providing their graduates with the tools in order for teachers to take part in classroom research and analyze their own instructional behaviors? Teacher training programs do not normally include consideration of teachers as researchers. More significantly, the current debate on democratic schooling suggests that teachers must learn right from pre-service training to become what Giroux (1986) and Aronowitz and Giroux (1985) have called transformative intellectuals, i.e, "one who excercises forms of intellectual and pedagogical practice which attempt to insert teaching and learning directly into the political sphere by arguing that schooling represents both a struggle for meaning and a struggle over power relations" (p. 215). Aronowitz and Giroux also characterize transformative intellectuals as capable of analyzing various interests and contradictions within society and articulating emancipatory possibilities, and working towards their realization.

In describing the contribution of current teacher training programs to the development of transformative intellectuals, Giroux explains that "when classroom life is discussed during college courses, it is presented as a one-dimensional set of rules and regulative practices, rather than as a cultural terrain where a variety of interests and practices collide in a constant and often chaotic struggle for domination. Unfortunately, this concept of schooling vastly contradicts what the student teacher often experiences during his practicum". Giroux asserts that many programs do not train teachers who can conceive their work as intellectual labour;
Instead, teachers become technicians or public servants whose role is to implement rather than to conceptualize pedagogical practice. Against this background, teachers form and fortify their own one-dimensional ideologies and experiences, there being no grounds upon which to question the dominant beliefs that shape the way in which they respond to, and influence student behaviors. It would seem therefore, that new learning should not be restricted to schools.

Perhaps even more urgent than in schools, learning is needed in teacher training institutions and policymaking organs. The same learning prescribed for schools should be done by colleges and departments in colleges that train teachers. If supervisors and researchers from these institutions are going to work with and learn from schools and classroom teachers, then they ought to be conversant with the lessons that schools and teachers have to teach. Furthermore, the teacher education programs must build more effective knowledge bases about teaching during teacher training. As Lanier and Floden (1978) and Lanier and Little (1986) have pointed out, little is known about transmitting the research knowledge in ways that allow teachers to successfully modify their practices. Without research in the methods of teaching in training, the results of research on teaching in classrooms cannot ultimately be used to improve teaching at all levels of schooling in order to develop tenable definitions of effective teaching.

Observing the work of four classroom teachers consistently for three years, revealed that there is no doubt that time is a very scarce commodity in schools. Any school which hopes to improve its practices should set up a system which not only involves all those within its walls but also adds no unnecessary burdens to personnel's timetables. School curriculums have recently expanded so that the pressure on time is reaching unbearable proportions. There is however, one caveat, namely, that no school is likely to evolve, discuss, implement and oversee a change to which there will be no internal dissension or opposition. The major weapons for dissent and opposition will rarely be new ones. They will concern the usual questions of lack of time, low pay for teachers, difficult management, making schools non-academic and implementing too
small a change to be effective. The three years of research in four schools regarding some of these problems, hold out only one piece of hopeful evidence, namely that in the highest and lowest achieving schools I was appraised of the value various activities many of which I thought had very fuzzy and dubious educational goals and objectives, if any. Similarly, I observed several practices which, in my mind, were ultimately detrimental to the development among students of a wide range of positive social and academic skills. As to time, in each school I observed and counted a lot of dead time - inside and outside classrooms. In my assessment, the most critical problem in schools was not lack of time and resources but lack of organization of available time and resources, in view of the objectives of schooling.

Any institution that attempts to develop and implement changes and practices on the basis of developing consensus among its participants, should also consistently work to avoid the twin traps of stagnation and coercion. On one hand, in a situation where change cannot be implemented because of lack of consensus, stagnation is likely to block future attempts to canvass consensus. On the other hand, coercion is likely to be used where, in the absence of agreement, consensus must appear to have been reached. Pragmatism should be sought in all deliberations. A practice should be adapted only because it enables its practitioners to do work more effectively, and where possible, efficiently. If there is doubt as to what is more effective, then some sort of alternative strategy or experimentation cannot be avoided. What should be avoided is the belief that any strategy will be effective for all schools and practitioners for all time.

The four teachers who participated in this research revealed that change was difficult to implement and sustain by individuals without the support of colleagues. But at the same time, teachers were willing to shoulder the perils of trying. They showed that given a viable alternative to what they were doing, they were willing to try it. I have no doubt that the majority of teachers in Kenya are more than equal to that task.

Seventy-eight newspaper articles in the two dailies, The Daily Nation, and The Standard, covering the period 1/05/1980 – 1/05/1982 provided public criticism, advise and expectations on the issue of school administration among many other educational issues. The official statements reproduced tended to be mainly “warnings” or “blastings” of headteachers and teachers. Seven examples are quoted below to show the general spirit and content of the statements from people at various levels of society.

1. Kamotho (Minister of Education), 1/5/80: *School Heads Urged to Teach.* “The Ministry expects in future, secondary school heads to be equipped with management skills, but they should realize that they are essentially education managers. The most important duty of school heads is to instill a feeling of involvement in both the teaching and non-teaching staff and to ensure that the curriculum is properly implemented.”

2. Kamotho (Minister of Education), 12/7/81: *Missing School Heads Condemned* “The Minister has blasted secondary school teachers especially headteachers who instead of doing their work at school were fond of travelling to town and markets and even engage in private business during working hours. The habit contributed greatly to poor performance by students in their examinations”.

3. Muchira (Letter the Editor), 16/1/82: *Transfer of Heads is Timely.* "... Some heads of schools in national and provincial schools have been transferred. This is a right move... Most of these heads are not in favour of the transfers. In fact they have approached politicians to suspend and eventually block these transfers. The truth about these heads is that some have made their mother tongue the official language and cannot imagine a transfer to other areas. Some national and boarding government schools are so corrupt that they fear their secret dealings being revealed. They have employed relatives and incompetent fellows. Tenders are given to relatives at inflated charges. The T.S.C. (Teacher Service Commission) should ignore any moves towards blocking these transfers. If the implementation takes long a few are going to formant trouble to discredit the new head".

4. Ingutya (Letters to Editor), 16/5/82: *Sack bad headteachers* “I note with concern the way some headteachers run schools. Some of these headteachers are very green in administration and have contributed directly to problems facing schools. The quarrel with the teachers under them and create disunity that hinders progress. I suggest that such irresponsible headteachers should be sacked.”
5. Yusuf (Education Official). 28/4/82: **Appointment of school heads is to be streamlined**...headmaster mattered a lot in all the performance of schools. If a headmaster was not on duty his teachers and even pupils come late contributing to poor examination results."

6. Leting (Education Official). 26/1/82: **Stop enrolling extra pupils**...Secondary school heads have been warned against over-enrolment. ...they should establish a communication link with students to avoid unnecessary and costly strikes."

7. Andahwa (Education Official): 5/5/82: **Ministry Official Slams Teachers**...has criticized some teachers whom he described as stumbling blocks in school administration. He said teachers regardless of their qualifications should co-operate with the headteacher to create discipline in schools. He warned that when teachers and headmaster were at loggerheads, the result was often indiscipline among students which affected the school performance.

Between 1/5/80 and 25/4/84 there were altogether 310 articles and letters to the editor referring to various aspects of education. Using content analysis, these articles were classified into three categories: those referring to administrative roles, functions, concepts and behaviours of headteachers; those referring specifically to the role of the headteacher in controlling teachers; and finally those referring to all other aspects of education such as curriculum, examinations, teacher training, textbooks, resources, distribution of teachers and other related issues. The chart below shows the number of articles in each of the three categories and the 9 main categories of personnel who authored these articles.
