A TECHNICAL DOCUMENT ISSUED BY THE  
INTERNATIONAL ATOMIC ENERGY AGENCY, VIENNA, 1976

### Summary

The subject breakdown of the AGRIS data base by categories interlinked with object and geographical codes is described in section 1. The use of these categories and codes in a mechanized information retrieval system is then considered.

The system is a modification of IBM's Information Retrieval and Management System (IRMS); it allows for batch processing on an IBM/360 or /370 computer operated under OS or VS. As IRMS was developed for use with a controlled vocabulary, the search possibilities on the AGRIS files are necessarily limited. An artificial vocabulary is presented, derived from the AGRIS subject categories, object codes, geographic codes, language codes, and bibliographic data: type of record, literary indicator, volume/issue number, and the country code of the submitting centre.

The use of the IRMS system for AGRIS is described in sections 2-10 with details of programming deliberately omitted. Program descriptions with data set definitions and file formats are presented separately in sections 11-13.

## Table of Contents

1.	<u>SUBJECT CATEGORIZATION</u>	1
1.1.	Subject Categories (Tag 008)	
1.2.	Object Codes (Tag 620)	
1.3.	Geographical Codes (Tag 620)

## 1. SUBJECT CATEGORIZATION

### 1.1. Subject Categories (Tag 008)

Access terms to the subject content of the AGRIS data base are provided in three major groups. The prime breakdown is given in Tag 008, where there is provision for a subject category code followed by supplementary subject category codes. In the printed output from the data base, AGRINDEX, the bibliographic citations are arranged under these sequential codes in the form of subject headings. If an item was assigned a supplementary category as well, then the record number only of that item appears under the appropriate category as "See also xxxxxx". It is evident that retrieval from AGRINDEX by this means would be a laborious operation. However, retrieval from the magnetic tape record is not restricted in this way, so that all citations indexed under a particular category code are equally retrievable.

We have then, in the subject category codes in Tag 008, a major broad retrieval vocabulary. The AGRIS subject categories are listed and described in AGRIS-3[9].

### 1.2. Object Codes (Tag 620)

The second group of access terms have been referred to as object codes, for want of a better expression. They are given in Tag 620, where it is possible to give these entries if required. The detail of the object codes will be found in the document AGRIS-3[9], as will the breakdown of the subject categories and the other codes yet to be mentioned. They consist basically of the names of animals and plants used by man and of foods; at the time of writing, the list is in the course of augmentation, but for practical

---

Note: In this document the letter O is then written as Ø when it is specifically distinguished from the digit 0.

purposes we shall consider the list as issued in March 1974 (rev.1).

The object code lists are constructed in such a way that a code may be provided for any crop or animal, although with differing degrees of precision. We have, for sake of example, the following grouping:

1100	<u>Tropical fruits - general</u>
1110	Avocadoes
1112	Bananas
1114	Date palms
1116	Guavas
1118	Litchis
1120	Mangoes
1122	Papayas
1126	Pineapples
1190	Tropical fruits - other

It is a simple matter to use the appropriate code for retrieving information relating to a crop that is named in this list, such as Mangoes. It is equally simple to use the code 1100 to retrieve papers dealing with tropical fruits in general, or papers in which a wide range of tropical fruits is mentioned. But if the object of our search is, say, Durians, then we have to query on code 1190. These 'other' groupings include all commodities that fall within a major group yet are considered as minor commodities in the world as a whole, no matter how important they may be in a particular region. Experience with the AGRIS files over the first twelve months of operation shows that these 'other' codings are in general little used, so that we may expect low levels of noise or irrelevant citations on retrieval.

One serious limitation in the use of object codes has been their restriction to a total of three. It is not infrequent for a paper to give information on more than three commodities, and the indexer has then been faced with the quandary of which commodities to index in Tag 620 and which to omit. Conversely, completeness of retrieval would be suspect. As of AGRINDEX volume 2 the limitation has been removed, so that as many codes may be entered in Tag 620 as the item warrants.

#### 1.3. Geographical Codes (Tag 620)

The third group are Geographical Codes, and they are also entered at Tag 620, in the last two positions. Unlike the Subject Categories and the Object Codes, the Geographical Codes are given in AGRIS-3 in the form of a structured thesaurus in order that their relationships may be made clear. They are fundamentally codes to political entities, subdivided in the case of large countries, but they also include codes for major quasi-political or physical groupings, such as G105 Francophone Africa, G800 South East Asia, and E037 SEAMEO. It is also possible to use a limited number of codes relating to physical geography, such as GZ40 Volcanic Areas.

#### 1.4. Use of AGRIS Categorization for Retrieval

As will be apparent when we come to Section 6, a query using the AGRIS/INIS modification of IRMS (Information Retrieval and Management System) employs Boolean logic, by which we may combine strings of codes, restrict the applications of certain codes, or ask for certain codes in combination with (or alternatively dis-associated with) stated other codes. The codes may be a carefully selected mixture

from any groups, so that, for instance, one could ask for citations dealing with the marketing (Subject Category E70) of pepper (Object Code 2320) in Java (Geographical Code G673).

The versatility of the system, within the limits of the AGRIS vocabulary as at present constituted, becomes at once apparent in use. The user will find that at first it is difficult to foresee exactly what his query will produce. There has been the problem of frequency, which is now no longer so important because figures are available from the AGRIS files. As is to be expected, the number of times that a term (a descriptor) is used in the data base is very variable; during the first twelve months of AGRIS, 0150 Rice was used 541 times, whereas 2387 Ylang-ylang had a frequency of 0. It therefore follows that a query on Ylang-ylang could consist of the single code 2387, but a query on Rice would necessarily have to be put in terms as specific as possible within the strictures of the system.

It is difficult to give a frequency figure below which the Object Code alone would suffice for retrieval purposes, especially as the user may not be aware of the frequency at the time of making the query. (Users of INIS have a great advantage over users of AGRIS at present in that they are able to consult a detailed thesaurus that includes frequencies.) However, if we consider the question in quantitative terms, it is unrealistic to retrieve listings of more than 30 or 40 citations.

#### 1.5. Bibliographic Data Elements

Sections 1.1-1.4 have been restricted to subject codings used in AGRIS, but it will be seen later that retrieval with the AGRIS modification of IRMS is not limited to those codes

alone. The AGRIS/IRMS thesaurus that is presented in this document also includes language codes, codes for types of record, codes for literary indicators, the volume/issue number, and the country code of the submitting centre. The intelligent use of these codes will give enhanced specificity to retrieval.

## 2. INTRODUCTION TO IRMS

The Information Retrieval and Management System - IRMS was originally developed by IBM for purposes which are evident from the name itself. The system is designed for carrying out retrieval based on controlled terminology, i.e., using the descriptors of a thesaurus as search points. Basically, IRMS works with three main disk files, the names and primary purpose of which are given below:

- a) IRMS Thesaurus - is used to check the correctness of the descriptors in a query and to replace them with their codes.
- b) Inverted file - is used to select among all the available documents those which are pertinent to the query processed, i.e., to carry out the actual retrieval.
- c) Bibliographic file - is used for printing the information on the retrieved documents necessary for their documentation.

At the AGRIS Input Unit in Vienna the system has been implemented and completed with an AGRIS-IRMS interface

which permits the use of different types of data elements as search points. With these modifications IRMS is being currently used for in-house search services on the cumulated AGRIS data base, as well as on the monthly AGRINDEX file. All examples and statistics given in this document refer to AGRINDEX volume 1.

All the following sections apply exclusively to the thus modified IRMS which is used at the AGRIS Input Unit in Vienna. The described AGRIS/IRMS system is derived from the INIS/IRMS system [8] modified for AGRIS needs.

### 3. SEARCH POINTS

In an IRMS query the following search points can be used:

- a) The object codes assigned to a document. The list of object codes is published in AGRIS-3[9].
- b) The geographic codes assigned to a document. The list of geographic codes is published in AGRIS-3[9].
- c) The subject categories, both primary and secondary, under which the document has been classified. Primary and secondary categories are treated in the same way and the program cannot distinguish between them. In addition, groups and series of categories, e.g., the A1-group or the C-series, are also search points.
- d) The language of the publication.
- e) The type of record, e.g. J for journal articles.

- f) The literary indicator, e.g. K for conference papers.
- g) The Agrindex volume/issue, half-volume and volume numbers. These are useful when it is necessary to limit the retrieval to a specific part of the whole data base.
- h) The country code (regional and/or national country codes).

For details on how to refer to the search points listed in a - g above see sections 4.1 and 4.2.

#### 4. AGRIS/IRMS THESAURUS

Entries in the IRMS Thesaurus consist of a term (up to 20 characters) and a five-digit code. The AGRIS/IRMS Thesaurus, i.e. term, code and the frequency of usage in the first year of AGRINDEX (~50,000 documents) are listed in Appendix 1. The IRMS Thesaurus for retrieval on the AGRIS files consists of two parts:

- A list of controlled terms for which numeric codes already exist in the original data base (e.g. object codes). The entries in this list are called 'descriptors'.
- A list of controlled terms for which the codes must be looked-up in a table at the time the inverted file is generated. The entries in this list are called 'pseudo-descriptors'. In order to differentiate between both lists, pseudodescriptors start with a dollar sign (\$) and are listed first in an alphabetical arrangement as Appendix 1.

#### **4.1. AGRIS Descriptors**

##### **a) Object Codes**

In general, two entries have been generated for each object code; the first one has as term the object code text as published in AGRIS-3 [9] or listed in the commodity index of AGRINDEX and as descriptor code the original object code is used. Some modifications will be necessary should AGRIS use non-numeric object codes. The second entry is a synonym of the first and has therefore the same code. The term however has the form OBJ=xxxx where xxxx means the object code. The second form will be preferred by the user in cases where the text is long.

The descriptors of the IRMS Thesaurus have a maximum length of 20 characters. Accordingly, text fields of object codes which are shorter or equal to 20 characters preserve their form in IRMS (e.g. BANANAS). If the text field includes a space, this counts as one character, e.g. SUGAR MAPLES.

Problems occur for long text fields: Cases of a text field longer than 30 characters (see Appendix 2.1) have been excluded altogether. No entry of the first type is generated.

Text fields with a length between 21 and 30 characters are truncated to 20 characters and are then included in the descriptor list if the truncation results in no ambiguity. Terms excluded from Thesaurus generation are listed in Appendix 2.1 and 2.2. In both cases, only an entry of the second type is generated (OBJ=xxxx).

b) Geographical Codes

For geographical codes the data base does not have a numeric code and therefore the entries for the geographic codes are generated as pseudodescriptors (see section 4.2). However for the reason of similarity to the object codes, entries to the descriptor list have also been generated. Since both use the same code the entries are synonyms. The form of the geographic code within the descriptor list is GEO=Gxxx, where Gxxx means the geographic code, with a numeric code generated by computer ( $\geq 80,000$ ). The system would allow the inclusion of the actual country name to be used as another synonym.

4.2. Pseudodescriptors

The second part of the AGRIS/IRMS Thesaurus consists of the pseudodescriptors. All terms in that list have a dollar sign (\$) in the first position followed by up to 19 characters. If the pseudodescriptor has the same code as a term in the descriptor list, then the pseudodescriptor is a synonym of the descriptor. The following pseudodescriptors are available:

a) subject categories

Pseudodescriptors of the type \$CAT=xxx where xxx is generally a subject category assigned to a document either as primary or as secondary one.

Note that for each specific subject category assigned three pseudodescriptors of this type are generated. They correspond to the category itself (e.g. \$CAT=A21 for A21), to the group of categories (e.g. \$CAT=A2 for A21, A22 and A20) and to the series of categories (e.g. \$CAT=A for all the

categories of the series A00, AGRICULTURE - general). Thus, retrieval at each level of generality can be done.

Note also that the pseudodescriptors in pairs like \$CAT=A20 and \$CAT=A2 are different and, when used in retrieval, select different subsets of the data base, e.g.:

\$CAT=A20 - subset  $S_1$  consisting of all documents classified under the general A20 category, either as primary or as secondary one.

\$CAT=A2 - subset  $S_2$  consisting of all the documents classified under categories belonging to the A2 group (A20, A21 and A22), no matter whether these were used as primary or secondary categories.

Obviously,  $S_1 \subset S_2$ .

b) language

Pseudodescriptors of the type \$LAN=XX where XX is the language of publication as used in Tag 600 (see section 2.600 in AGRIS-1 [10]) e.g.

\$LAN=EN

\$LAN=ES

etc.

c) type of record

Pseudodescriptors of the type \$TYP=X where X

is the type of record (see Tag 008 in the AGRIS Worksheet header reproduced in Appendix 3), e.g. \$TYP=R for reports.

d) literary indicators

Pseudodescriptors of the type \$LIT=X where X is a literary indicator circled in Tag 008 (see the AGRIS Worksheet header reproduced in Appendix 3), e.g. \$LIT=Y for progress reports. More than one literary indicator is allowed for the same document and in this case more than one pseudodescriptor of this kind is generated, e.g. \$LIT=K and \$LIT=E for a conference paper published with summary included.

e) volume/issue number

Pseudodescriptors of the type \$VOL=XXXX where XXXX is the Agrindex volume/issue, half-volume and volume numbers. Three pseudodescriptors of this kind are generated by IRMS for each document on the file, e. g. for a document published in Agrindex vol.1 no.3 they are

- \$VOL=01/03 - indicates the exact issue of publication;
- \$VOL=01/A - Indicates that the document was published in the first half of vol.1; (similarly, it would be \$VOL=1/B for documents published in the second half of vol.1);
- \$VOL=05 - indicates the volume of publication

f) country code \*

Pseudodescriptors of the type \$CC=xx where xx is the two-character code issued by ISO in April 1975, extended by the regional country codes defined by the AGRIS coordinating center.

Entries in the inverted file are generated from the first two characters of the TRN and from the optional subfields for country codes in Tag 008.

## 5. THE IRMS BIBLIOGRAPHIC FILE

This is a direct-accessible file containing information which allows the identification of the documents to be retrieved.

The file contains the complete bibliographic citations arranged in the same way as in Agrindex.

Records on the bibliographic file are referred to by means of an IRMS-generated Document Access Number (DAN) starting with 1 for any IRMS system. IRMS DANs are then different from AGRIS RNS, if AGRIS RNS have been deleted from the file or if the IRMS system does not include the complete AGRIS cumulative file.

---

\* As of AGRINDEX volume 2.

## 6. REQUEST STRUCTURE

Queries are entered into the computer on punch cards and processed in batch. Each request consists of:

- a) a title card;
- b) descriptor card(s);
- c) query card(s).

The general card format is

1	2	3		73	74	76	80
I	D		variable text - see <u>6.1</u> , <u>6.2</u> and <u>6.3</u>	0	5	R R N N N N	

where:

ID - card type identifier; can have one of the following values:

- 00 for the title card;
- 01,02,...,15 for the descriptor cards;
- 99 for the query card(s).

05 - must be punched in cols 74-75 of all cards.

RR - two-digit retriever's code

NNN - three-digit query number.

Note: No two queries in a batch with the same retriever's code and query number are accepted.

### 6.1. Title Card

This is the first card of each query. Its format is as follows:

1	2	3	4	13	14	17	18	69	70-73	74	80
0	0	=			QID				RET	0 5 R R N N N	

Card Col. No.      Content

14-17                QID Query identification  
(4 character code)

70-73                RET Retriever identification  
(3 character code)

4-13 }                May be used  
18-69 }                for any kind of identification.

### 6.2. Descriptor Cards

As already mentioned, both descriptors and pseudodescriptors form part of the IRMS Thesaurus and can equally be used in query formulation. For the sake of brevity we refer to "descriptors" only but, actually, both descriptors and pseudodescriptors are meant.

The descriptors used in a search are divided into groups. The descriptors in each group are linked by one of the two logical operators:

AD        (logical "and"), and

ØR        (non-exclusive logical "or").

Each group may contain up to 10 descriptors. There may be up to 15 groups. Thus, a query profile may contain up to 150 descriptors.

The groups are numbered from 01 to 15. The descriptor cards must be given in ascending group number.

Each descriptor card has the following format:

1	2	3	4	5	6	7	8	9	Descriptors	73	74	80
G	G	,	Ø	P	,	P	=			0	5	R R N N N

optional

where

GG is the group (01 to 15) number

ØP is the logical operator used (either AD or ØR)

P if col. 6 and 7 contain ', P' the descriptors of this group are printed with the descriptor codes (see Appendix 4.1). If the Thesaurus print is not desired, col. 6 contains the equal sign (=) and the descriptors start in col. 7.

The descriptors (twenty characters at most!) are punched, beginning in column 7 resp. 9 with the Thesaurus print option and separated by commas. No blanks should either precede or follow the commas. A period (.) must follow the last (or only) descriptor on a card.

If the descriptor field (cols. 7-73) is not enough for entering all the descriptors of a group, up to three additional cards bearing the same group number may be used. Their format is exactly the same as described above. Each of them must have a period after the last (or only) descriptor and, therefore, there can be no transfer of descriptor parts from one card to another. Thus, the order of the descriptor cards (up to four) within a group is irrelevant.

Note that if a group consists of one descriptor only, either of the two logical operators (AD or ØR) may be used. The results obtained will be identical for each case.

### 6.3. Query Card(s)

The query card is used to express the actual question by means of combining the various descriptor groups with the logical operators AD ("and"), ØR (non-exclusive "or") and NØ ("and not"). It has the following format:

1	2	3	4		73	74	80
9	9	,		nnnn=Boolean expression		0 5 R R N N N	

where:

99 is the query-card identifier.

nnnn is the output definition parameter. It is a decimal number which may consist of 1-4 digits, i.e.  $1 \leq nnnn \leq 9999$ . This number must be followed by an equal sign (=) after which the Boolean expression starts (no blanks allowed).

If the Boolean expression is too long and cannot be entered into cols 4-73 of the query card, a continuation card (one only!) may be used. Its format is:

1	2	3	4		73	74	80
9	9	,		Boolean expression (continued)		0 5 R R N N N	

The output definition parameter nnnn governs the print-out of the documents retrieved: if the actual number of these documents (either at an intermediate or at the final step of the query execution) is less than or equal to nnnn, then the program prints out the corresponding bibliographic citations; otherwise it just indicates the number of documents retrieved and the printing is suppressed. Thus, the output definition

parameter acts as a sort of safety factor against printing long lists of irrelevant documents in case of wrong or badly formulated queries.

The Boolean expression is constructed in accordance with the following rules:

- a) The simplest Boolean expression consists of a primary. A primary is either
  - i) a single group number or
  - ii) another expression enclosed in parentheses
- b) More complicated expressions are formed by linking two or more primaries with logical operators. If the primaries linked are more than two, all the operators used must be of the same type.
- c) No more than two levels of nested parentheses are admitted.
- d) A logical operator may appear only between two primaries, i.e. no two operators can be adjacent to each other.
- e) The operators which can be used are:
  - i) AD (logical "and");
  - ii) ØR (non-exclusive "or");
  - iii) NØ (logical "and not").

All desired operators must be specified explicitly.

- f) The parentheses used must be balanced, i.e. the number of open parentheses must be equal to that of the closed ones.

- g) A group number in a Boolean expression may appear only once. If a second use of the same set of descriptors is required, they must be repeated a second time on the descriptor cards with different group number.

Examples

I. Valid IRMS Boolean expressions:

01  
01AD02  
(01ØR02)AD03  
((01AD02)ØR(03AD04))AD05  
(01AD02)NØ03  
01NØ02  
(01NØ02)AD03

II. Invalid IRMS Boolean expressions:

01AD02ØR03	Two operators of different types (rule b).
0102	Missing (i.e. not explicitly specified) operator (rule e).
01ADNØ02	Two consecutive operators (rule d).
(01AD(02ØR(03AD04)))	Three levels of nested parentheses (rule c).
((01ØR02)AD03	Unbalanced parentheses (rule f).
(01AD02)ØR(01AD03)	Group number used twice (rule g).

Two sample queries are given in Appendix 4.

## 7. IRMS FORMALISM VERSUS BOOLEAN ALGEBRA

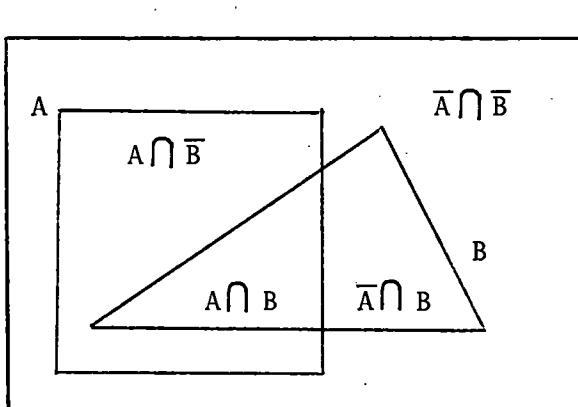

The IRMS query formulation is actually just a way of expressing Boolean operations between classes.

Each descriptor in the descriptor cards represents the class of all documents in the data base to which that descriptor has been assigned.

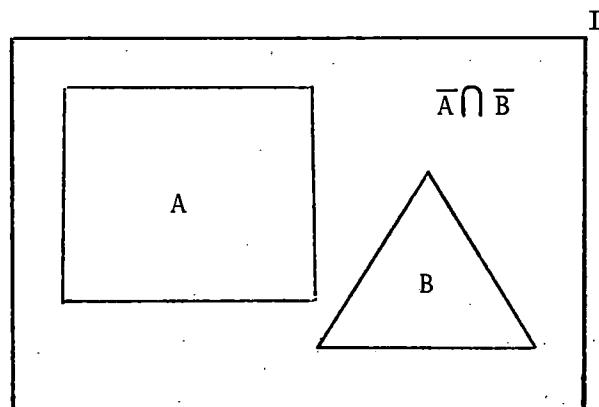

Each group is the class resulting from the Boolean sum (operator OR) or the Boolean product (operator AND) of the classes represented by the descriptors in that group.

The Boolean expression in the query line, finally, represents the class resulting from the specified Boolean operations between the various groups. This is actually the class of documents to be retrieved.

The following diagrams give a schematic picture of the three Boolean operations:

Case 1:  $A \cap B \neq 0$

Case 2:  $A \cap B = 0$

where:

- I is the class of all the documents in the data base;
- A is the class of documents indexed with descriptor A;
- B is the class of documents indexed with descriptor B;
- $\bar{A}, \bar{B}$  are the classes of documents not indexed with descriptors A and B respectively;

$\cap$  is the Boolean product or class intersection operator;  
 $\cup$  is the Boolean sum or class union operator.

The result of the Boolean operation  $A \cup B$  is illustrated by the sum of areas  $A \cap \bar{B}$ ,  $A \cap B$  and  $\bar{A} \cap B$  in case 1 and, respectively, by  $A$  and  $B$  in case 2.

If group number 01 and 02 are assigned to descriptors A and B respectively, then one-to-one correspondence between IRMS and Boolean operators can be established:

$$01AD02 \equiv A \cap B \quad (7*1)$$

$$01\emptyset R02 \equiv A \cup B \quad (7*2)$$

$$01N\emptyset 02 \equiv A \cap \bar{B} \quad (7*3)$$

The symbol  $\equiv$  means "is equivalent to".

In Appendix 5 some of the most useful laws of Boolean algebra are listed. Many of the limitations imposed by rules 6.3.a - g can be overcome with the help of these laws. For instance, the expression

$$01AD(02AD((03AD04)\emptyset R(05AD06))\emptyset R(07AD08)),$$

although quite legitimate in Boolean algebra, violates both rule b (AD and  $\emptyset R$  operators in the outermost pair of parentheses) and rule c (three levels of nested parentheses). One level of nested parentheses is avoided if we write it as

$$01AD((02AD03AD04)\emptyset R(02AD05AD06)\emptyset R(07AD08)),$$

but group 02 is now repeated twice (rule g). Therefore, a new group 09 equivalent to group 02 is introduced and the expression takes its final form

$$01AD((02AD03AD04)\emptyset R(09AD05AD06)\emptyset R(07AD08)).$$

Another way of dealing with the same expression would be to split the original request into two subqueries:

- a) 01AD02AD((03AD04)ØR(05AD06));
- b) 01AD07AD08;

the final answer to the request would then be the sum of answers to a and b above.

## 8. SEARCH EXECUTION AND OUTPUT

### 8.1. Execution

IRMS carries out the search from left to right along the Boolean expression, in one or more steps. Each step produces its own output.

The number of steps can, to a certain extent, be controlled by the retriever and depends on the way in which the Boolean expression of the query card(s) is formulated. This control is limited because it must be exercised within the rules 6.3.a - g; in particular, rule c which does not allow more than two levels of nested parentheses is of primary importance.

The number of execution steps is equal to the number of queryline primaries which

- a) are not enclosed in a higher level of parentheses;
- b) are linked by the operators AD or NØ.

If the operator linking the primaries is  $\emptyset R$ , or the Boolean expression consists of a single primary, then the search is carried out in one step. Some illustrative examples are given in the following table:

<u>Boolean expression</u>	<u>Total number of steps</u>	<u>Step expressions</u>
01	1	01
01 $\emptyset R$ 02	1	01 $\emptyset R$ 02
((01 $\emptyset R$ 02)AD03)N $\emptyset$ 04	2	1) ((01 $\emptyset R$ 02)AD03) 2) ((01 $\emptyset R$ 02)AD03)N004
01AD02	2	1) 01 2) 01AD02
01AD02AD03AD04	4	1) 01 2) 01AD02 3) 01AD02AD03 4) 01AD02AD03AD04
((01 $\emptyset R$ 02)AD(03 $\emptyset R$ 04))	1	((01 $\emptyset R$ 02)AD(03 $\emptyset R$ 04))

To reduce the amount of printout when the search is carried out in steps, it is advisable to arrange the Boolean expression in such a way that the primaries with the lower probabilities are searched first (see sections 8.2 and 9).

### 8.2. Search Output

The search program processes the queries in the order in which they are submitted and, for each query, produces the output described below. Appendix 4 gives sample computer printouts.

A listing of the request cards comes first. If any error is detected by the program, an error message is printed and, most probably, no further output is produced. Appendix 6 gives a list of error messages which can be produced by the search program.

If no error is detected the output proceeds by steps. Intermediate steps are indicated by a line reading "TEMPORARY ANSWER"; this message is followed by the number of documents retrieved (N=...) and by a list of descriptor groups on which that particular step is based (QU=.....). The last (or only) step starts with a similar line reading "LAST ANSWER"; no group list is given here since all the groups participate in selecting the last answer.

Because of the way the steps are defined, the documents retrieved at a given step are always a proper or improper subset of the documents retrieved at any of the preceding steps. The bibliographic citations are, therefore, only printed for the first step which retrieves a number of documents less or equal to the output definition parameter.\* After the step indicator line (either "TEMPORARY ANSWER" or "LAST ANSWER") the bibliographic citations follow. They consist of:

- a) A header line containing
  - i) The IRMS Document Access Number (DAN); note that IRMS DAN may be different from the AGRIS RN (see section 5).
  - ii) The AGRIS RN.
  - iii) The volume/issue numbers.
  - iv) The codes of primary and secondary (if any) subject categories in their correct order.
  - v) An indication of the type of record in the form of the corresponding pseudodescriptor (see section 4.2.c) but without the leading \$.

---

\* At previous steps where the number of documents retrieved exceeds the value of the output definition parameter as specified on the query card the printing of the bibliographic citations is suppressed (see section 6.3).

- vi) An indication of the literary indicator(s) assigned (if any) in the form of the corresponding pseudodescriptors (see section 4.2.d) but without the leading \$.
- vii) The country code of the submitting centre - for a regional input centre the national country code follows in parentheses if given in the AGRIS data base.\*

b) The bibliographical data which will be printed as in Agrindex.

For each subsequent step (if any) the program prints a list of the DANs only.

#### 9. ESTIMATION OF THE OUTPUT DEFINITION PARAMETER nnnn

The simplest way to estimate the output definition parameter nnnn is the "try and guess" method. However primitive it may seem, its precision increases with the retrieval experience gathered. It is based on intuition whose importance can hardly be over-estimated. Unfortunately, no manuals on how to improve one's intuition are available.

We shall, therefore, concentrate on a simple statistical method which can give us a probable value for nnnn. At least the order of magnitude of this value is usually correct. Statistically nnnn can be expressed as

$$nnnn = P_n \cdot N \quad (9*1)$$

where  $N$  is the number of documents in the data base.

$P_n$  is the probability to meet in the data base a combination of descriptors satisfying the query.

---

\* As of AGRINDEX volume 2.

For a given data base N is a known quantity. To evaluate  $P_n$  we start with evaluating the probabilities  $P_d$  of descriptors forming the query:

$$P_d \approx \frac{F_d}{N} \quad (9*2)$$

where  $F_d$  is the descriptor's frequency of usage which can be taken from Appendix 1.

Then we proceed with evaluating the probabilities  $P_k$  of the groups of descriptors in the query. For a group ØR operator:

$$P_k \approx \sum_{i=1}^{m_k} P_{d_i} \quad (9*3or)^*$$

where  $k$  is the group number(01 to 15);

$m_k$  is the number of descriptors in group no.  $k$ ;

$P_{d_i}$  is the probability of the  $i$ -th descriptor calculated according to (9\*2)..

For a group with AD operator:

$$P_k \approx C^{m_k-1} \prod_{i=1}^{m_k} P_{d_i} \quad (9*3ad)^{**}$$

\* Terms of the type  $-C_{12}P_{d_1}P_{d_2}$  (where  $C_{12}$  is the correlation factor and the product represents the probability of simultaneous assignment of descriptors  $d_1$  and  $d_2$ ) are neglected in (9\*3or), as they normally are second-order corrections.

\*\* The  $(m_k-1)$ -th degree of the average C-factor substitutes here the product of actual correlation coefficients ( $C_{12}$ ,  $C_{13}$ ,  $C_{23}$ , etc.).

where  $C$  is an average correlation factor; for the AGRIS file,  $C$  is unknown.  $C$  is estimated to be between 2 and 3.

Readers not familiar with the mathematical notations may find the following explanations useful:

$\sum_{i=1}^{m_k}$  is the sum of the terms following the symbol for values of  $i$  running from 1 to  $m_k$ ;

$\prod_{i=1}^{m_k}$  is the product of the terms following the symbol for values of  $i$  running from 1 to  $m_k$ .

We can now calculate the probability  $P_n$  of the Boolean expression in the query line as:

$$P_n \approx B_n \quad (9*4)$$

where  $B_n$  is an arithmetical expression obtained from the Boolean one in the query line by means of the following transformations:

- a) The operators AD, ØR and NØ are replaced with  $\cap$ ,  $\cup$  and  $\neg$  according to formulae (7\*1), (7\*2) and (7\*3) respectively;
- b) Simple group numbers ( $k$ ) are substituted by their probabilities ( $P_k$ ) and overscored group numbers ( $\bar{k}$ ) by  $1-P_k$ ;
- c) Each  $\cup$  operator is replaced with a plus sign (+) and each  $\cap$  operator with multiplication (x) accompanied by a factor  $C$ .

Thus, the value of  $P_n$  can be calculated and then substituted in (9\*1).

## 10. RESPONSE EVALUATION

Due to a number of reasons the response obtained may be both comprehensive and correct only by chance. These reasons are, e.g., errors in indexing (under- or over-indexing), inadequacies of the indexing tools, variations in interpreting the documents by the indexers who prepared the input, errors in query formulation, etc. Some definitions will be given below which can help us to evaluate numerically the response obtained.

Query target is a subset of the entire data base I. T consists of all the documents relevant to the question asked. The number of documents in the query target T is denoted as  $N_T$ .

Query yield is another subset Y of the same data base I. Y consists of those documents which have actually been selected (retrieved) as a result of the query. The number of documents in the query yield Y is denoted as  $N_Y$ .

Let us suppose that the query yield can e.g., by manual scanning be subdivided into:

-Hits, i.e. documents retrieved which are relevant to the questions asked,

and

-Noise, i.e. documents retrieved which are not relevant to the questions asked. If  $N_H$  and  $N_N$  are the numbers of documents in the hits and in the noise respectively, then evidently

$$N_Y = N_H + N_N$$

We have now all the quantities necessary to define the two main numerical characteristics of the response:

Recall ratio (completeness ratio) R is the ratio of the number of relevant documents retrieved  $N_H$  to the number of all the relevant documents in the data base  $N_T$

$$R = \frac{N_H}{N_T} \quad (10*1a)$$

Relevance ratio (precision ratio) P is the ratio of the number of relevant documents retrieved  $N_H$  to the number of all the documents retrieved  $N_Y$

$$P = \frac{N_H}{N_Y} \quad (10*2a)$$

Very often both recall and relevance are expressed in percent:

$$R\% = 100 \frac{N_H}{N_T} \% \quad (10*1b)$$

$$P\% = 100 \frac{N_H}{N_Y} \% \quad (10*2b)$$

By definition

$$0 \leq R \leq 1$$

$$0 \leq P \leq 1$$

and, accordingly,

$$0 \leq R\% \leq 100$$

$$0 \leq P\% \leq 100$$

It is clear from the above definitions and formulae that the relevance ratio can be calculated on the basis of

the query results only, while calculation of the recall requires some knowledge of documents which have not been retrieved. Hence, the relevance ratio is much easier to obtain. Precise calculation of the recall ratio is only possible for small data bases which allow for reasonably quick manual scanning. In practice the recall is estimated approximately - either by extrapolating  $N_T$  as the limit of  $N_Y$  for a series of queries encompassing each other or by manual scanning of a small part of the entire data base.

For a given data base the two quantities, R and P, are not independent of each other. Usually, an attempt to increase the recall (e.g. by broadening the query profile) leads to decreasing the relevance and vice versa. The relative speeds of these changes are an intrinsic characteristic of the data base itself. For a "good" data base reasonable gains in R (respectively, P) should not lead to very big losses in P (respectively, R). In any case, this interconnection is of statistical nature and should be averaged over a large number of queries. No attempts should be made to assess the quality of the file on the basis of an individual query or a small group of queries.

## 11. COMPUTER HARDWARE AND SOFTWARE REQUIREMENTS

The IBM system was originally written for DOS [5, 6, 7] and has been modified for INIS requirements in DOS [1, 2]. This DOS version has then been converted to OS [8] whereby only those parts needed for INIS-SDI purposes have been included, a special job set up is needed to generate retrospective files. This package has subsequently been modified for AGRIS requirements. Another simplification is that query input can be on cards only and not on console as in DOS.

Furthermore some blocking factors have been increased so that the programs are better suitable for IBM 3330 disk drives.

An additional program has been written which converts AGRIS output tapes to an internal format, which is the input format to the retrieval system. This means that for AGRIS Member States a complete set of programs would be available, which allows to process IRMS queries on AGRIS output tapes. As additional input file the AGRIS descriptor file and the pseudodescriptor list is required.

#### 11.1. Hardware

- IBM 360 or 370 operated under OS (or VS)
- IBM 3330 or 2314 disk drive
- Private disk space for dictionary file, bibliographic and inverted files, and work space (sort work areas, etc.)
- 120k partition
- One magnetic tape unit (preferably 9-track)
- Card reader
- Line printer (preferably with upper-lower case characters)

#### 11.2. Software Requirements

Assembler, PL/1(F), IBM sort utility program, general IBM utility programs (like IEBGENER).  
AGRIS/IRMS program package.

#### 11.3. Input Data Files

Agrindex file (resp. AGRIS output tape)  
AGRIS descriptor file  
Pseudodescriptor file  
Query cards (to be supplied by the user)

## 12. PROGRAM DESCRIPTION

The general flow chart is given as a figure in Appendix 7.1, an example of job control is listed in Appendix 8.

### 12.1. CVAG - Convert AGRIS Output Tapes to Internal Format (not used at AGRIS Input Unit)

Program CVAG reads the AGRIS output tapes and converts the data to the internal format used for processing at the AGRIS Input Unit.

This program is similar to program CVMI described in IAEA-INIS-14 (Rev.1) [3] which converts INIS input tapes. The main program may be used without change, however subroutine NXTTAG has to be modified in order to generate an AGRIS master file and not the INIS bibliographic check file.

#### Data Set Definitions

MAGTP	AGRIS output tape (for format see FAO-AGRIS-7 (Rev.0) [4])
SYSPRINT	System messages
ATMF	Agrindex file (output, max. record length 3500 characters, variable length records)

### 12.2. BIBTXT - Create Bibliographic Text File

Program BIBTXT reads the Agrindex file (output of program CVAG, see section 12.1), and creates the lines of text which the search program SEARCH (see section 12.6) will print in reply to queries. The text lines produced by BIBTXT are processed by program CVTBIB (see section 12.3) which creates the IRMS bibliographic file.

Output of this program is a file with fixed length records (record length 61), formatted as in the printed version

of Agrindex.

The record format is as follows:

t	text
---	------

1 2

61

The first character t of each record identifies blocks of lines as follows:

t = 'R' this record is the first line of the bibliographic description. It contains the RN of the document in pos. 2 to 7, the main subject category in pos. 8 to 10, and the literary indicators in position 11 (8 bits, a bit per indicator).

'R'	RN	CAT	LIT	not used
-----	----	-----	-----	----------

1. 2 7 8 10 11

61

t = 'X': this record is the last line of a document and contains the information of tag 620 (object codes and geographic codes). Cols. 2-61 are blank if tag 620 was not present.

t = ' ': bibliographic text lines.

For any given AGRIS record there is one R-type record. No external routines are used.

#### Data set definitions

SYSPRINT PL/I messages

ATMF Agrindex file (input, max. record length 3500 characters, variable length records)

ATMXF Bibliographic text file (output, record length 61 characters, fixed length records)

### 12.3. CVTBIB - Convert Bibliographic File

This program creates the IRMS bibliographic file (BIBF) with an index file to the bibliographic file (XBIBF), and the IRMS direct search file.

It also assigns IRMS Dan's (Document Access Number). The IRMS DAN may differ from the AGRIS RN number, since the AGRIS RN number may have gaps due to record deletions, or does not start with 1, if not the complete AGRIS file is used for the IRMS data base.

If there is no parameter on the exec-card given, the DAN starts with 1; if the program is used to create a file to be added to a existing data base, the parameter on the exec-card must indicate the highest DAN of the existing data base (see Appendix 7.2).

The bibliographic file (BIBF) is created by using as input the fixed-size Agrindex file generated by BIBTXT (section 12.2) and the Agrindex file (generated by section 12.1). If several issues are processed, single Agrindex files have to be reassembled to represent one large Agrindex file. By the use of program CXBIB (see section 12.8) there is a possibility to update old IRMS files (see job flow in Appendix 7.2).

The record format of the bibliographic files is as follows:

DAN	SEQ	Text
1	3	4 5 6

65

where DAN is stored in binary (24 bits)

SEQ is the record sequence (packed). In the AGRIS implementation the record sequence is assigned as follows:

100-199 bibliographic data lines  
200 text of tag 620

"Text" is the text as generated by program BIBTXT (except for the first line of each bibliographic record which contains the RN, the AGRIS type of record, the literary indicators (as letters K L U ... etc.), the volume/issue number of Agrindex in which the document was announced (see description of header-line in output, section 8.2.a.i-vii), and the country code(s).\*

The bibliographic file is physically written by routine WRTBIB, which also creates an index to it, so that it can be accessed directly by the SEARCH program. The bibliographic file is written in BSAM access method. There exist two versions of WRTBIB, one for 3330, one for 2314 disk drives:

- a) 3330 disk drives: 200 records are constituted to one physical block. The block length is therefore 13,000; suitable for IBM 3330 disk drives.
- b) IBM 2314 disk drives: 100 records are constituted to one physical block. The block length is therefore 6,500; suitable for IBM 2314 disk drives.

The index consists of a table containing one entry for each block of the bibliographic file; each entry has the following format:

Highest DAN in block (binary)	Relative track address TTR
-------------------------------	----------------------------

only the left three bytes of relative address (TTRZ) is recorded.

1

3 4

6

---

\* As of AGRINDEX volume 2.

The index file is generated in QSAM, thus allowing the blocking to be done at execution time (e.g. block size = 6,000, record size = 6, record format = fixed-blocked).

The second output of program CTVBIB is the direct search file (DRSRCH) which contains the descriptor number (DNR) assigned to each DAN. This file, after a sort by DNR, is used as input to the IRMS program INV1 which creates the IRMS inverted file. The object code numbers are extracted from tag 620.

In addition to the object code numbers, the program also creates entries in the direct search file records for the following data elements:

- volume/issue numbers
- subject categories
- type of records
- literary indicators
- language
- country code of inputting centre
- geographical codes

In order to be able to retrieve by these data elements without changing the search program, they are treated as if they were normal descriptors. For this purpose a list of pseudodescriptors corresponding to the data elements mentioned above has been set up and each of the first six types of pseudodescriptors has been assigned a code number greater than 90000 (so that no conflicts arise with thesaurus descriptors). For the geographical codes a code greater than 80000 has been assigned identical with the corresponding code in the descriptor list; the descriptor and the pseudodescriptor entries for the geographical codes are consequently synonyms.

Program CVTBIB reads the file of pseudodescriptor data

and generates a table. This table is used to look up the code of a pseudodescriptor. The pseudodescriptor file must be sorted by ascending alphabetical sequence.

Description of the pseudodescriptors:

For each volume/issue number the program constructs a pseudodescriptor corresponding to the volume (e.g. \$VOL=06), to the first or second half of the volume (\$VOL=xx/A and \$VOL=xx/B), and to the exact volume/issue number (\$VOL=xx/nn), (see section 4.2.e).

For each subject category assigned the program generates three pseudodescriptors corresponding to the category, subcategory, and sub-subcategory (see section 4.2.a). For example, the category A21 generates the following pseudodescriptors.

\$CAT=A, \$CAT=A2, \$CAT=A21

It is easy to see that pseudodescriptor \$CAT=A2 will retrieve all documents in any A2x category, whereas \$CAT=A20 retrieves only documents assigned specifically to category A20.

For the type-of-record (see section 4.2.c) the program generates a pseudo-descriptor of the form: \$TYP=X where X is the type of record as indicated on the AGRIS work sheet (e.g. \$TYP=R).

For each literary indicator (see section 4.2.d) assigned the program generates a pseudo-descriptor of the form: \$LIT=X, where X is the literary indicator as cycled on the AGRIS work sheet (e.g. \$LIT=K).

For each language (see section 4.2.d) given in tag 600 the program generates a pseudodescriptor of the form: \$LAN=LL, where LL is the 2 character language code translated to upper case characters.

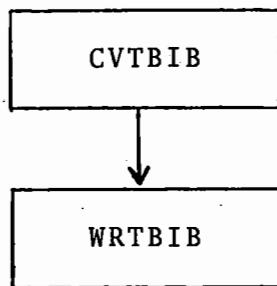

If a language in tag 600 is not found in the pseudo-descriptor table (new language or spelling error) the program issues an error message and assigns in lieu the pseudo-descriptor \$LAN=OTHER.

The internal procedure NUMBER looks up each pseudo-descriptor in the pseudodescriptor table and stores the corresponding number in the table ADT. This routine checks for duplicates and ignores them (e.g. if categories A15 and A17 are assigned to the same document \$CAT=A and \$CAT=A1 are generated twice). The pseudodescriptor numbers stored in ADT are then added to the direct search file after processing of each document. The direct search file has the following format:

DNR dec. fixed (5.0)	DAN bit (24)
-------------------------	-----------------

1                   3 4                   6

Program hierarchy:

External routines:

#### WRTBIB

Calling sequences: CALL WRTBIB (TXT)  
CALL CLSBIB

Entry point WRTBIB writes the text field TXT (char(65)) onto file BIBF and records the index entry information onto file XBIBF.

Entry point CLSBIB fills the last block with dummy information (hexadecimal FF), writes it onto disk, closes the files and finishes the index file in the same way. If this call is omitted, the bibliographic and the index file would be incomplete.

#### Data set definitions

SYSPRINT	PL/1 messages
BIBF	Bibliographic file (output, record length= 65 characters, 3330 version: block size=13000 characters, 2314 version: block size= 6500 characters)
XBIBF	Index to bibliographic file (output, record length=6 characters)
DRSRCH	Direct search file (output, record length=6 characters)
ATMF	Agrindex file (input)
ATMFX	Agrindex text file (input)

#### 12.4. INV1 - Create Inverted File

INV1 is essentially the original IRMS program with the two modifications as described in INIS/IRMS [8]. A further simplification was that the part for retrospective search which updates an existing old inverted file has not been converted to OS. INV1 is an Assembler program, no external routines are used. The direct search file (generated by CVTBIB) after a sort by descriptor number and DAN, serves as input.

Output of INV1 is the IRMS inverted file (OMFILE), which has the following format:

DNR	DAN <sub>1</sub>	DAN <sub>2</sub>	padding
-----	------------------	------------------	---------

1      3 4      6 7      9

93

For one descriptor number up to 30 DAN's (in ascending sequence) are entered in one record. If there are less than 30 DAN's the record is padded with hexadecimal 'FF', for more than 30 DAN's a second record is used with the same DNR in position 1 to 3.

The records are blocked by program (25 records per block), the highest DNR within each block supplies an entry for an index file. This index file (X2ØFILE) has a record length of 7 (3 bytes for DNR, 4 bytes for relative track address TTRZ), and is blocked by program (40 records per block); the highest DNR within each index block gives an entry to another index file (record length 7, blocksize 1400).

#### Data set definitions

IDFILE	Direct search file (input, sorted by DNR and DAN)
ØMFILE	IRMS inverted file (output, block size=2325)
X2ØFILE	Index 2 to IRMS inverted file (output, record length=7, block size=280)
X1ØFILE	Index 1 to index 2 (output, record length=7, block size=1400 bytes)

Please note that the inverted file with its indexes are named differently when used as input in program SEARCH.

## 12.5. DICTO - Create IRMS Thesaurus

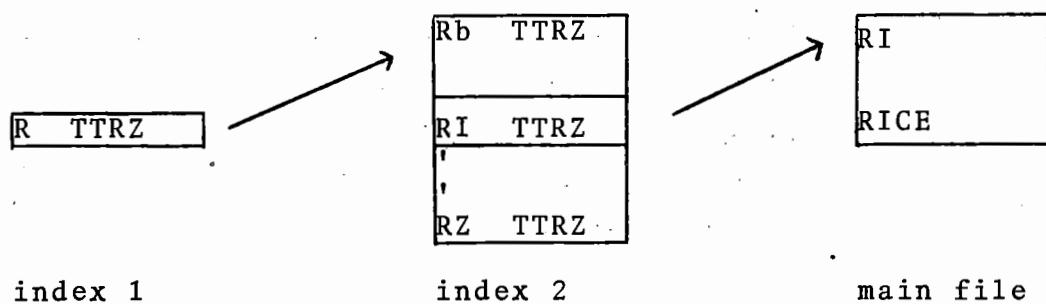

DICTO is a modified version of the original IRMS DICT1 program. All program parts used for updating an existing IRMS Thesaurus file have not been converted to OS.

Program DICTO enables one to create the IRMS Thesaurus as needed by the SEARCH program using as input the deck of pseudodescriptors and the INIS Thesaurus. The pseudo-descriptor deck must be sorted in ascending alphabetical sequence.

The AGRIS descriptors are truncated to 20 characters; those which give an ambiguous character string are listed (Appendix 2.2). In these cases the synonym form OBJ=xxxx has to be used.

The program constructs two indexes to access the file, the first index has the starting character of the term as entry, which points to the second index, where two starting characters of the term form the entry, which then points to the file.

Examples for term 'RICE':

Index 1 has record length 5 and consists of one block of 150 bytes, index 2 has record length 6 and may have up to 30 blocks, each one consisting of 150 bytes.

No external procedures are used.

### Data set definitions

ØFILE	Output print file (list of terms excluded because of ambiguity)
ØMFILE	AGRIS/IRMS Thesaurus file (output)
X2ØFILE	Index 2 to ØMFILE (output, record length=6 block size=150)
X1ØFILE	Index 1 to index 2 (output, record length=5 block size=150)
INISTH	AGRIS descriptor file (input)
INISAT	Pseudodescriptor file (input), same as used in program CVTBIB (see section <u>12.3</u> )

Please note that the descriptor file with its indexes are named differently when used as input in program SEARCH.

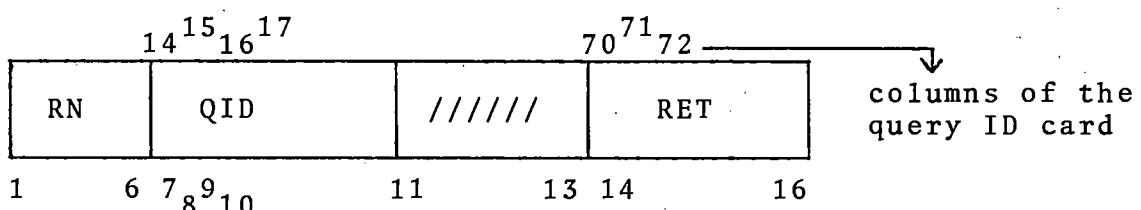

### 12.6. SEARCH - Retrieval Program

This is a modified version of the original IRMS search program. The following characteristics are valid for the OS version.

- a) TABLE1 of the inverted file is core resident (as in DOS).
- b) TABLE1 of the IRMS Thesaurus is core resident (as in DOS).
- c) The bibliographic file is accessed via a block index (similar to the track index of the DOS version) rather than an index sequential organization as in the IBM version.

The index is kept core resident although it is rather large. An area of 24000 bytes is provided. This allows for 4000 index entries, i.e. 4000 tracks can be addressed. The maximum area to be allocated is 32K and 5300 tracks can be addressed. For making a full 3330 disk drive addressable, some program modifications are necessary, e.g. the use of a double index is recommended.

The SEARCH program creates a file (RNFILE) containing for each document retrieved in a given run the AGRIS RN and the identification. It has the following format:

where RN: AGRIS RN number

QID: Query identification (col 14-17 of the query ID-card)

RET: Retriever identification (col 70-72 of the query ID-card)

For QID and RET see section 6.1.

The RNFILE is usually not used in the AGRIS/IRMS system in contrary to the INIS/IRMS system [8], where a special program is used to print the RNFILE. Therefore in AGRIS, output is usually suppressed by setting it to 'DUMMY'.

There is however one practical use in cases where the output is too large to be reasonably printed, one may suppress the printing of the normal output and assign the RNFILE data set to the printer (see Appendix 4.3). In that case one receives at least the list of RN numbers.

No external procedures are used for program SEARCH.

SEARCH is not able to execute correctly more than one NØ operator at a step.

There exist two versions of program SEARCH for the 3330 disk drives and the 2314 disk drives.

#### Data set definitions

BIBF	Bibliographic file (input)
XBIBF	Index to bibliographic file (input)
IMFILE	IRMS inverted file (input)
IFX1I IFX2I	} Indexes to IMFILE (input)
IFILE	IRMS dictionary file (input)
X1IFILE X2IFILE	} Indexes to IFILE (input)
OPFILE	Printed output, DCB=(RECFM=FA, BLKSIZE=133)
TRSIT WRKFIL	} Work files
RNFILE	RN-file (output)
CARDF	Query input cards (input)

#### 12.7. CXBIB - Create Index of Bibliographic File

The original IBM program package provided for creation of a retrospective data base by adding to an existing data base new information. This part has not been converted to OS. Instead a special job flow (see Appendix 7.2) has been used to perform this task without repeating on the old data base the most time consuming programs, namely CVTBIB and BIBTXT. Only the new data are sent through program BIBTXT and CVTBIB with a parameter indicating the DAN to start with. The old bibliographic file and the new one are read by the additional program CXBIB which creates a common bibliographic file with an index to it. Furthermore the old direct search file (sorted by DNR) must be kept to be merged with the new search file. The output of the merge step is then routed to program INV1.

CXBIB is a PL/1 program, and has no external procedures.

Data set definitions

SYSPRINT	System messages
BIBF1 }	Bibliographic files (input)
BIBF2 }	
BIBF	Bibliographic file (output)
XBIBF	Index to bibliographic file (output)

Since the index is not created by the Assembler macro instruction NOTE, the files can intermediately be created on magnetic tape.

Please note that the method does not take care of changed record or deleted records; i.e. any documents to be deleted from the data base are not removed!

13. FILE FORMATS

(\* means changeable at execution time via DD statement)

1. Agrindex file (same format as INIS Atomindex file described in IAEA-INIS-14(Rev.1) [3]
2. Bibliographic Text File  
Record size: 61  
Block size: 6100\*
3. Bibliographic File  
- main file: Record size: 65  
Block size: 13000 for 3330 disk drives

APPENDIX 2: LIST OF OBJECT CODES EXCLUDED

2.1: List of object codes with text too long for inclusion in AGRIS/IRMS Thesaurus

**TERMS LONGER 30 CHARACTER (EXCLUDED FROM THESAURUS GENERATION)**

02000	SUGAR AND STARCH CROPS - GENERAL
07000	TEMPERATE TREE FRUITS - GENERAL
09000	TEMPERATE BERRY FRUITS - GENERAL
14000	LEGUMINOUS GRAINS AND VEGETABLES - GENERAL
14900	LEGUMINOUS GRAINS AND VEGETABLES - OTHER
16000	GREENS AND LEAFY VEGETABLES - GENERAL
16900	GREENS AND LEAFY VEGETABLES - OTHER
19000	PASTURES AND FEED CROPS - GENERAL
19900	PASTURES AND FEED CROPS - OTHER
23900	FLAVOURING AND PERFUME PLANTS - OTHER
24000	RUBBER AND WAX PLANTS - GENERAL
30000	FOREST AND ORNAMENTAL TREES - GENERAL
31000	CONIFERS AND OTHER GYMNOSPERMS - GENERAL
31900	CONIFERS AND OTHER GYMNOSPERMS - OTHER
34000	PLANTS UTILIZED BY MAN - OTHER GENERAL
34900	PLANTS UTILIZED BY MAN - OTHER SPECIFIC
73000	INSECTS USED FOR BIOLOGICAL CONTROL
74000	INSECT POLLINATORS (OTHER THAN BEES)
85000	REPTILES AND BATRACHIONS - GENERAL
85900	REPTILES AND BATRACHIONS - OTHER
86000	AQUATIC INVERTEBRATES - OTHER GENERAL
86900	AQUATIC INVERTEBRATES - OTHER SPECIFIC
87000	AQUATIC VERTEBRATES - OTHER GENERAL
88000	ANIMALS UTILIZED BY MAN - OTHER GENERAL
88600	PET ANIMALS (OTHER THAN CATS, DOGS, RABBITS)
88900	ANIMALS UTILIZED BY MAN - OTHER SPECIFIC
91000	FRUIT AND VEGETABLE PRODUCTS - GENERAL
91200	CANNED OR DRIED FRUITS AND VEGETABLES
91300	PROCESSED FRUITS AND VEGETABLES
91900	FRUIT AND VEGETABLE PRODUCTS - OTHER
92000	CEREALS AND BAKERY PRODUCTS - GENERAL
92900	CEREALS AND BAKERY PRODUCTS - OTHER
93000	SUGAR AND STARCH PRODUCTS - GENERAL
93900	SUGAR AND STARCH PRODUCTS - OTHER
98000	FISH AND MARINE FOOD PRODUCTS - GENERAL
98500	FISH AND MARINE FOOD PRODUCTS - OTHER
99300	FRUIT-BASED NON-ALCOHOLIC DRINKS

2.2: List of ambiguous terms excluded from AGRIS/IRMS  
Thesaurus

DESCRIPTORS WITH MULTIPLE DESCRIPTOR NUMBERS

BEVERAGE PRODUCTS - OTHER	9.950
BULBOUS VEGETABLES - OTHER	1.790
CUCURBIT VEGETABLES - OTHER	1.829
DOMESTICATED BIRDS - OTHER	6.900
DOMESTICATED MAMMALS - OTHER	5.900
OIL HERBS AND BUSHES - OTHER	390
OIL-PRODUCING TREES - OTHER	329
TAN AND DYE PLANTS - OTHER	2.690

#### APPENDIX 4: SAMPLE QUERIES

The queries have been executed with the AGRIS data base of volume 1 with 48,326 retrieval documents.

##### 4.1. Sample Query 1

Query: Data on cultivation and protection of asparagus

Comments: This sample illustrates the use of the highest hierarchical levels of the subject categories to capture data throughout more specific levels.

The operator in group 02 could as well be specified as AD, since there is only one operator.

##### 4.2. Sample Query 2

Query: Bibliographies in languages other than English relating to oil or fibre crops except cotton.

Comments: The sample illustrates the need for all required object codes to be included. Since one group may contain only up to 10 descriptors, the object codes related to all oil and fibre crops have been spread in group 01 to 04. Group 05 and 07 could be merged as one group with OR operator, but it is good practice to combine only logically connected terms in one group.

## APPENDIX 5: SOME USEFUL LAWS OF BOOLEAN ALGEBRA

1.  $a \subset b \equiv a \cap b = a$
2.  $a \subset b \equiv a \cup b = b$
3.  $a \cap b \equiv b \cap a$
4.  $a \cap (b \cap c) \equiv (a \cap b) \cap c \equiv a \cap b \cap c$
5.  $a \cup b \equiv b \cup a$
6.  $a \cup (b \cup c) \equiv (a \cup b) \cup c = a \cup b \cup c$
7.  $a \cap \bar{a} = 0$  (no documents retrieved)
8.  $a \cup \bar{a} = I$  (all documents retrieved)
9.  $\bar{a} \cup \bar{b} \equiv (\bar{a} \cap \bar{b})$
10.  $\bar{a} \cap \bar{b} \equiv (\bar{a} \cup \bar{b})$
11.  $(\bar{a} \cup \bar{b}) \equiv \bar{a} \cap \bar{b}$
12.  $(\bar{a} \cap \bar{b}) \equiv a \cup \bar{b}$
13.  $(\bar{a} \cap \bar{b}) \equiv \bar{a} \cup b$
14.  $a \cup (a \cap b) \equiv a$
15.  $\bar{a} \cap \bar{b} \cap \bar{c} \cap \dots \equiv (\bar{a} \cup \bar{b} \cup \bar{c} \cup \dots)$
16.  $(a \cup b) \cap c \equiv (a \cap c) \cup (b \cap c)$

Symbols used:

- $\cup$  logical "or"
- $\cap$  logical "and"
- $\bar{\phantom{x}}$  (overscore) logical complement  
(i.e. the subset of documents where a descriptor is not present)
- $\subset$  "implies" (subset-symbol)
- $\equiv$  "is equivalent to"

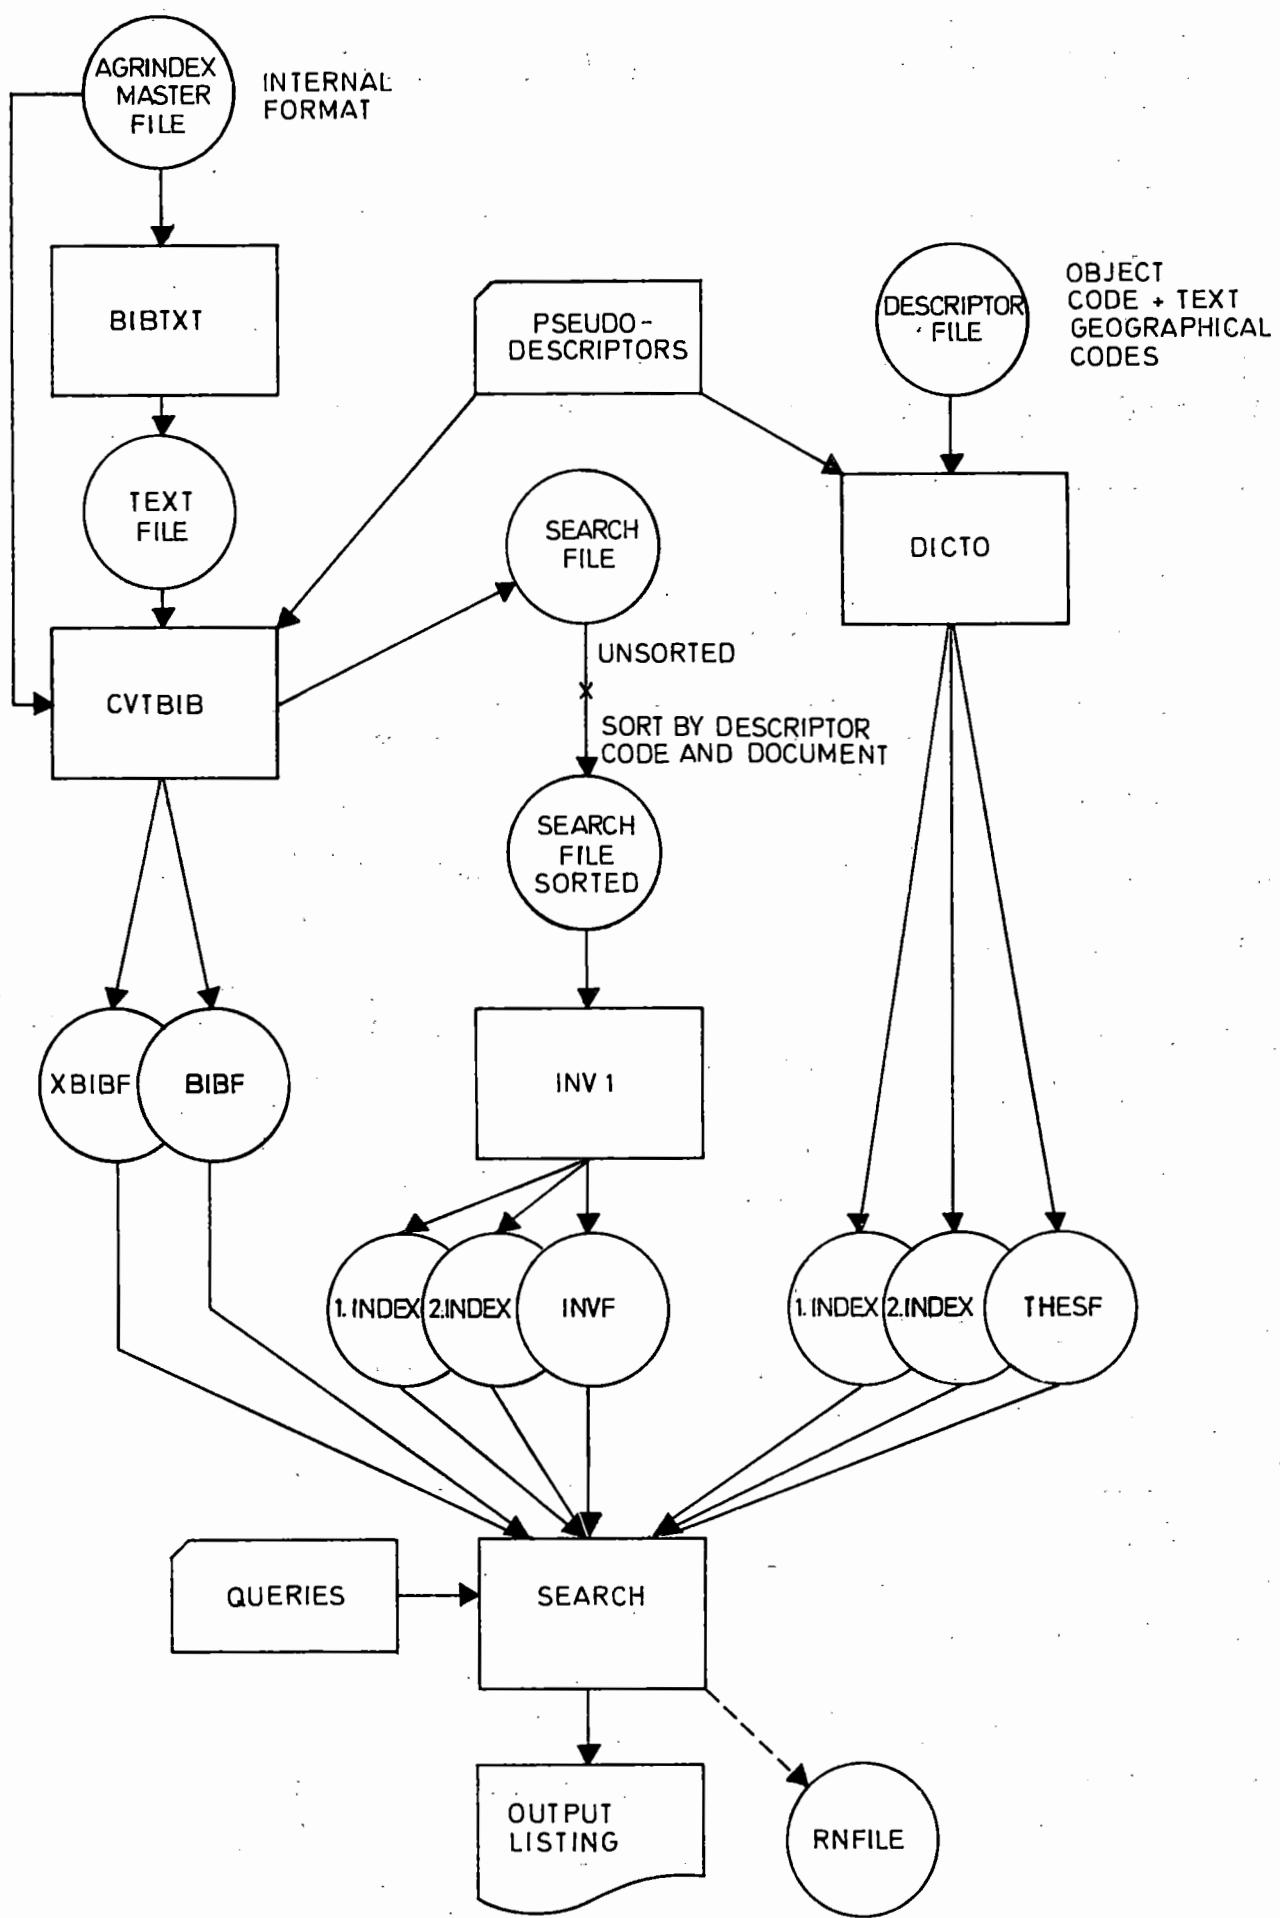

## APPENDIX 6: LIST OF ERROR MESSAGES

<u>Message</u>	<u>Description</u>	<u>Action taken by program</u>
CARD CODE IS WRONG	Columns 74-75 do not contain '05'	The card is ignored. This may, however, generate other error messages
NOT IDENTIFICATION LINE	The first card is not a title card (ID=00)	The query is not processed
SEQUENTIAL ERROR IN REQUEST	The cards are out of sequence. Either the group numbers are not in ascending order or two queries have the same query number (col. 76-80)	The query is not processed
MORE THAN FOUR LINES IN GROUP xx	A group may not consist of more than 4 cards	The excess card(s) are ignored and processing continues (the descriptors on the excess cards will not participate in the search)
MORE THAN TWO LINES IN QLINE	The number of query cards may not exceed two	The excess card(s) are ignored and processing continues
GROUP NUMBER xx IS WRONG	The group number must be between 01 and 15	The card is ignored
THERE IS NO QLINE	The query card is missing	The query is not processed
QLINE IS WRONG	The query card contains a format or syntax error (e.g unbalanced parenthesis)	Only the correct portion of the query card is processed (if possible)
GROUP USED SEVERAL TIMES IN QLINE	A given group number may not be used more than once in the query. Define a new group number with the same descriptors and resubmit the query	Only the correct portion of the query card is processed

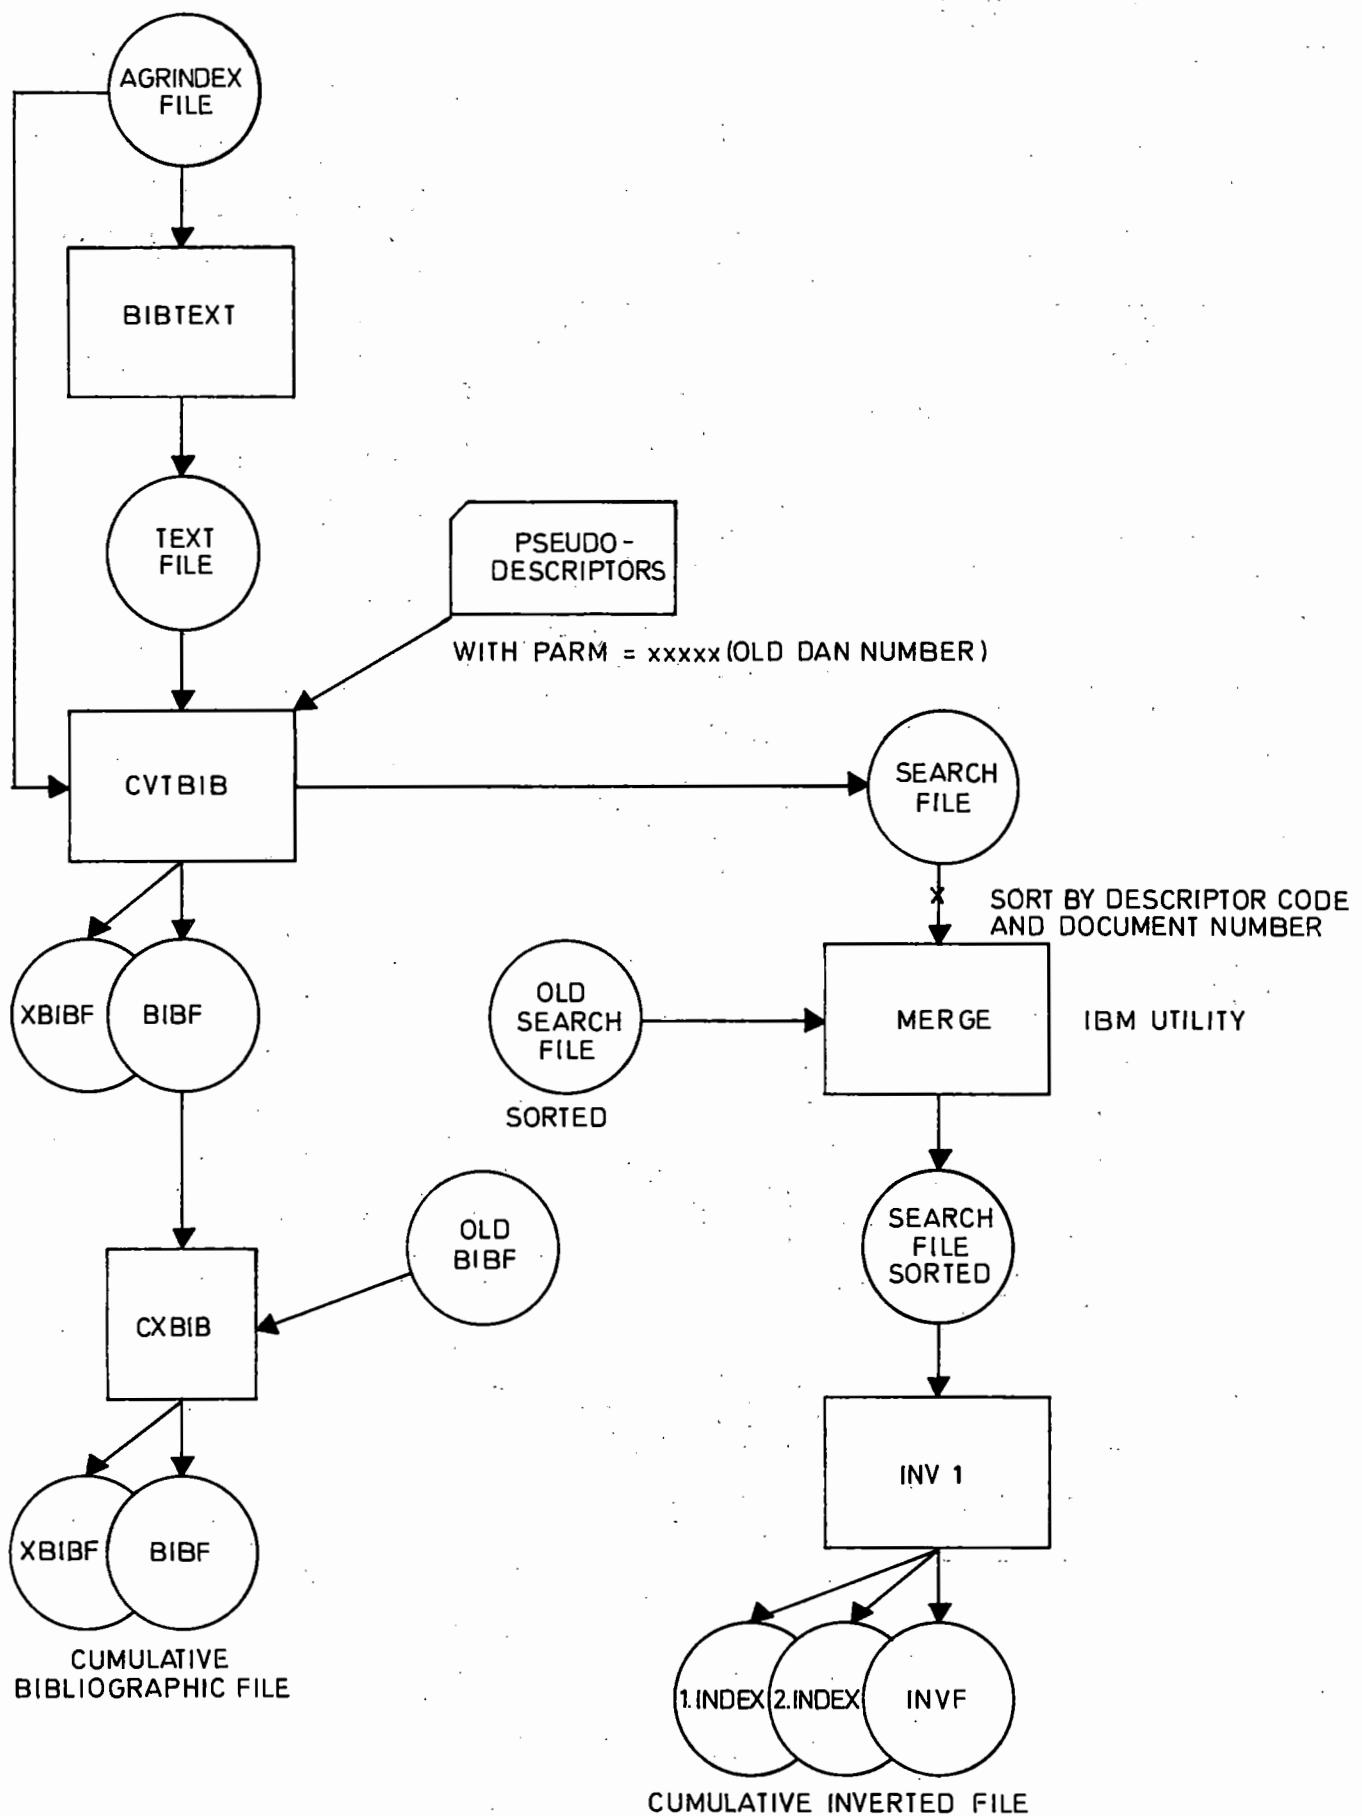

<u>Message</u>	<u>Description</u>	<u>Action taken by program</u>
GROUP NUMBER IS WRONG IN QLINE	A group number used in the query is not between 01 and 15	Only the correct portion of the query card is processed (if possible)
ERRONEOUS LOGICAL CONNECTOR IN QLINE	Either a wrong logical operator has been used (i.e. other than AD, ØR, or NØ), or a level of parenthesis contains two different logical operators. For example the following expression would produce this message: 01AD02ØR03 The above should be corrected to either of the following (whichever applies): (01AD02)ØR03 or 01AD(02ØR03)	Only the correct portion of the query card is processed
UNDEFINED GROUP IN QLINE	A group number used in the query has not been defined	Only the correct portion of the query card is processed
ERRONEOUS LOGICAL CONNECTOR IN GROUP xx	The descriptor cards may only contain one of the logical operators AD or ØR	The query is not processed
GROUP FORMAT xx IS WRONG	Format error in a descriptor card (the correct format is described in Section 6.2 of this report)	The query is not processed
DESCRIPTORS WRONG OR UNKNOWN IN GROUP xx	The descriptor card xx contains a descriptor longer than 20 characters, or the last descriptor in the card is not followed by a period	The query is not processed

<u>Message</u>	<u>Description</u>	<u>Action taken by program</u>
X DESCRIPTORS WRONG OR UNKNOWN	Descriptor x is not in the IRMS Thesaurus	The query is not processed
MORE THAN TEN DESCRIPTORS IN GROUP xx	A descriptor group may not contain more than 10 descriptors. Split the group into two or more different groups	The excess descriptors are ignored and processing continues
DNR nnnnn UNKNOWN	The descriptor with descriptor number nnnnn has not been used in indexing the documents in the data base. This has no effect on the query processing. In order to find out which descriptor causes this message, use the thesaurus print option (see Section 6.2) to receive the list of descriptors and des- criptor codes.	The query is processed correctly

APPENDIX 7.1: GENERATION OF IRMS FILES AND SEARCH PROGRAM

APPENDIX 7.2: GENERATION OF RETROSPECTIVE IRMS FILES

## APPENDIX 8: JOB CONTROL STATEMENTS

The following printouts show the job control statements used at the AGRIS Input Unit for the monthly retrieval services.

Three jobs are to be executed in sequence, whereby no permanent disk space is used. The data files are kept as a multi-file volume on magnetic tape (reel number 001471).

- Job 1 XFES30 generates the AGRIS/IRMS Thesaurus and its two indexes.
- Job 2 XFES31 generates the bibliographic file with its index and the inverted file with its two indexes.
- Job 3 XFES32 restores the disk files (program INALLOC) from magnetic tape and executes the SEARCH program.
- Program INALLOC is equivalent to 8 IEBGENER steps however faster since 1 step only is executed.

## Generation of AGRIS/IRMS Thesaurus

```
//XFES30 JOB (W2631,FE,T),537-SCHMID,
