Factors associated with short birth interval in low- and middle-income countries: a systematic review

Juan Pimentel^{1,2,3*} , Umaira Ansari⁴, Khalid Omer⁴, Yagana Gidado⁵, Muhd Chadi Baba⁵, Neil Andersson^{1,4} and Anne Cockcroft^{1,4}

Abstract

Background: There is ample evidence of associations between short birth interval and adverse maternal and child health outcomes, including infant and maternal mortality. Short birth interval is more common among women in low- and middle-income countries. Identifying actionable aspects of short birth interval is necessary to address the problem. To our knowledge, this is the first systematic review to systematize evidence on risk factors for short birth interval in low- and middle-income countries.

Methods: A systematic mixed studies review searched PubMed, Embase, LILACS, and Popline databases for empirical studies on the topic. We included documents in English, Spanish, French, Italian, and Portuguese, without date restriction. Two independent reviewers screened the articles and extracted the data. We used the Mixed Methods Appraisal Tool to conduct a quality appraisal of the included studies. To accommodate variable definition of factors and outcomes, we present only a narrative synthesis of the findings.

Results: Forty-three of an initial 2802 documents met inclusion criteria, 30 of them observational studies and 14 published after 2010. Twenty-one studies came from Africa, 18 from Asia, and four from Latin America. Thirty-two reported quantitative studies (16 studies reported odds ratio or relative risk, 16 studies reported hazard ratio), 10 qualitative studies, and one a mixed-methods study. Studies most commonly explored education and age of the mother, previous pregnancy outcome, breastfeeding, contraception, socioeconomic level, parity, and sex of the preceding child. For most factors, studies reported both positive and negative associations with short birth interval. Shorter breastfeeding and female sex of the previous child were the only factors consistently associated with short birth interval. The quantitative and qualitative studies reported largely non-overlapping results.

(Continued from previous page)

Conclusions: Promotion of breastfeeding could help to reduce short birth interval and has many other benefits. Addressing the preference for a male child is complex and a longer-term challenge. Future quantitative research could examine associations between birth interval and factors reported in qualitative studies, use longitudinal and experimental designs, ensure consistency in outcome and exposure definitions, and include Latin American countries.

Trial registration: Prospectively registered on PROSPERO (International Prospective Register for Systematic Reviews) under registration number [CRD42018117654](#).

Keywords: Birth intervals, Developing countries, Breastfeeding, Pregnancy outcome, Systematic review

Background

Adequately spaced births allow women to recover from previous pregnancies, but both too short or too long intervals lead to adverse maternal, perinatal, neonatal, and child health outcomes [1]. The World Health Organization (WHO) currently recommends an interval between the last live birth and the next pregnancy of at least 24 months [2], a birth interval of 33 months.

A meta-analysis published in 2006 reported that short (< 18 months) and long (> 59 months) intervals between two consecutive pregnancies were associated with preterm birth, low birth weight, and being small for gestational age [1]. Another meta-analysis found an association between a birth interval of less than 24 months and infant mortality [3], and others have reported an association between short birth intervals and schizophrenia in the offspring [4]. Shorter interpregnancy intervals are associated with premature membrane rupture, abruptio placentae and placenta previa, and uterine rupture among women with previous caesarean section [5]. Similarly, very long birth intervals (> 5 years) are associated with adverse maternal outcomes such as pre-eclampsia [6].

A systematic review published in 2012 suggested potential mechanisms for the adverse consequences of short birth interval [7]. These include poor maternal nutritional status and folate depletion, suboptimal lactation for the newborn, cervical insufficiency, infections, sibling competition, incomplete healing of the uterus, and abnormal remodelling of endometrial blood vessels. Short birth intervals may also limit the opportunities for economic development of women and their families [8].

One estimate suggests that around 2 million of the 11 million deaths per year of children under 5 years old could be prevented by avoiding birth intervals of less than 2 years [9]. International bodies such as the WHO and USAID have called for further research and actions to address short birth interval [2, 10].

Short birth interval is more common among women in low- and middle-income countries, where an estimated 17% of married women of reproductive age are reported to have unmet needs for family planning [11]. For example, the 2018 Nigerian Demographic and Health Survey

(DHS) reported that 19% of married women have unmet family planning needs [12]. Similarly, the 2013 Nigerian DHS found that 23% of women had a birth interval of less than 24 months for their last two births and 62% had an interval of less than 36 months [13].

Several systematic reviews have examined the consequences of birth interval for maternal and child health outcomes [1, 3, 5]. Although a number of individual studies reported on potentially causal factors associated with short birth interval [8, 14, 15], we are not aware of any systematic review that has examined the determinants of short birth interval. Understanding the actionable factors related to short birth interval is crucial to inform efforts to address the problem, particularly in low- and middle-income countries. We therefore conducted a systematic review to examine the factors associated with short birth interval in low- and middle-income countries.

Methods

We registered the protocol prospectively on PROSPERO (International Prospective Register for Systematic Reviews) under registration number CRD42018117654 [16]. Our research question was: what are the factors associated with birth interval in low- and middle-income countries? We report our systematic review following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines [17]. Our PRISMA checklist is available in Additional file 1.

Search strategy

Using key terms specific to each database, Boolean operators, and truncators, we developed the search strategy with the collaboration of an experienced librarian from McGill University. We included PubMed, Embase, LILACS, and Popline, which is a database specialized in maternal and reproductive health containing grey literature [18]. Our search strategy is available in Additional file 2.

Eligibility criteria

We used the following inclusion criteria: (i) experimental or observational studies reporting a measure of association (such as relative risk, odds ratio, or hazard ratio),

qualitative studies, and mixed methods studies; (ii) studies in English, Spanish, French, Italian, and Portuguese; (iii) studies conducted in low- or middle-income countries according to the World Bank classification [19]; (iv) exposure: including but not limited to community-based factors, demographic factors, epidemiologic factors, socio-economic factors, environmental factors, and sociocultural factors; (v) outcome: length of intervals between births to women in the population in any time unit. We did not have restrictions regarding the year of publication.

We excluded theoretical publications, quantitative studies reporting only proportions or *p*-values (without a measure of magnitude of association), studies from high-income countries, studies using “birth spacing” as a synonym for contraception use, and studies exploring factors associated with the interval between marriage and first birth.

Data collection

Using the open-source systematic review web application Rayyan [20], two independent researchers (JP and UA) screened the titles and abstracts and included only the potentially relevant articles. They resolved discrepancies by discussion and consensus, involving a third party (AC) in case of no resolution. Subsequently, we retrieved the full-text articles of all the selected references and removed the duplicates using EndNote X8.2. JP and UA performed the final selection of studies using an eligibility format based on the elements listed in the search strategy. We piloted this format on 5% of the retrieved studies.

The research team collectively designed the data extraction form based on the variables that would answer the research question, in an iterative process with regular meetings to discuss and update the form. JP and UA independently piloted the data extraction form on 5% of the studies to determine its appropriateness. They then extracted data from the included studies and conducted a cross-check review to verify the quality and accuracy of the extracted data.

We extracted the following data when available: basic study information (title, year of publication, country, authors, type of document, and journal); population and setting (sample size, age range, ethnicity, study setting); study methods (aim, study design, unit of analysis, statistical methods, qualitative methods used, ethical approval); and results (exposure and outcome definition, crude and adjusted measure of association, confidence interval, number of participants with/without the outcome in the exposed/non-exposed groups, qualitative findings).

We planned to conduct a quantitative synthesis only if the included studies were sufficiently homogeneous and of adequate quality. As definition of factors was heterogeneous and study quality was variable, we performed a narrative synthesis of the quantitative findings and an

inductive thematic analysis [21] on the results of the qualitative studies.

Methodological quality

To assess the quality of the included studies, we used the 2018 Mixed Methods Appraisal Tool (MMAT), a quality appraisal instrument for systematic reviews including qualitative, quantitative, and mixed methods studies [22]. Researchers have reported on this tool's efficiency, reliability [23], and content validity [24]. JP and UA independently performed the quality assessment of each publication.

Results

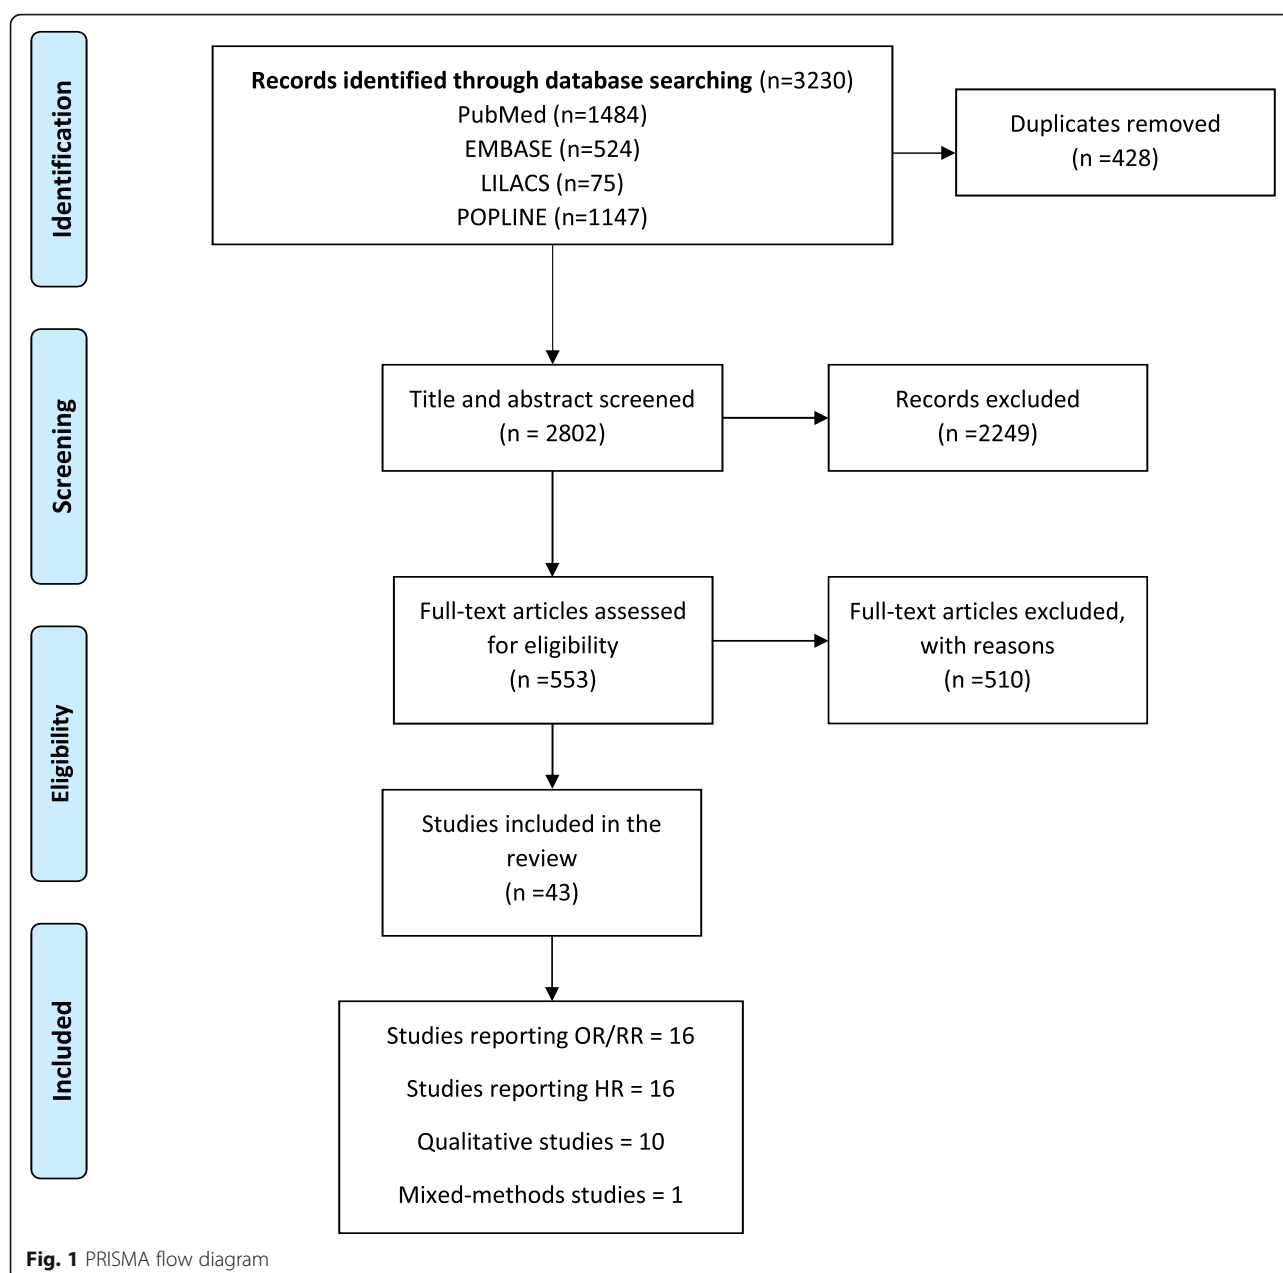

From an initial 2802 documents identified by our search, 43 studies remained after screening and assessment (Additional file 3). We categorized these into four subgroups: studies reporting odds ratio (OR) or relative risk (RR); studies reporting hazard ratio (HR); qualitative studies; and mixed methods studies (Fig. 1 and Additional file 4).

Figure 2 shows the countries where the studies took place. Africa produced the most studies (21/43), followed by Asia (18), and the Americas (four). The countries with the most studies were Nigeria (five studies), Tanzania (five studies), and India (four studies). Some 14 studies were published after 2010, 14 studies between 2001 and 2010, eight studies between 1990 and 2000, and seven studies before 1990. Four documents were reports (two from grey literature) and the remainder were journal articles. Most of the quantitative studies used a cross-sectional design (24/32) and sample sizes ranged widely from 134 to 64,943 (Table 1).

Studies reporting OR/RR

Some 11 studies reported factors associated with short birth interval after adjusting for confounders. The most commonly reported factors were age of the mother (seven studies), education of the mother (six), and contraception use (five). Five studies defined short birth interval as < 24 months, while two studies used < 33 months and < 36 months, respectively (two studies did not provide their definition of short birth interval). For all factors but length of breastfeeding (three studies) and sex of the previous child (two studies), researchers reported mixed results. Table 2 shows the associations reported between factors and short birth interval.

Seven studies found an association between a short birth interval and a younger age of the mother. Among these publications, two studies explored age at last delivery, one study explored the age of the mother at the moment of the study, and the remaining studies did not specify a definition of age of the mother. Two studies reported an association between a short birth interval and older age of the mother (one study explored age at first pregnancy).

Three studies found an association between short birth interval with shorter duration of breastfeeding. One study found more short birth interval with no breastfeeding as opposed to exclusive or mixed breastfeeding.

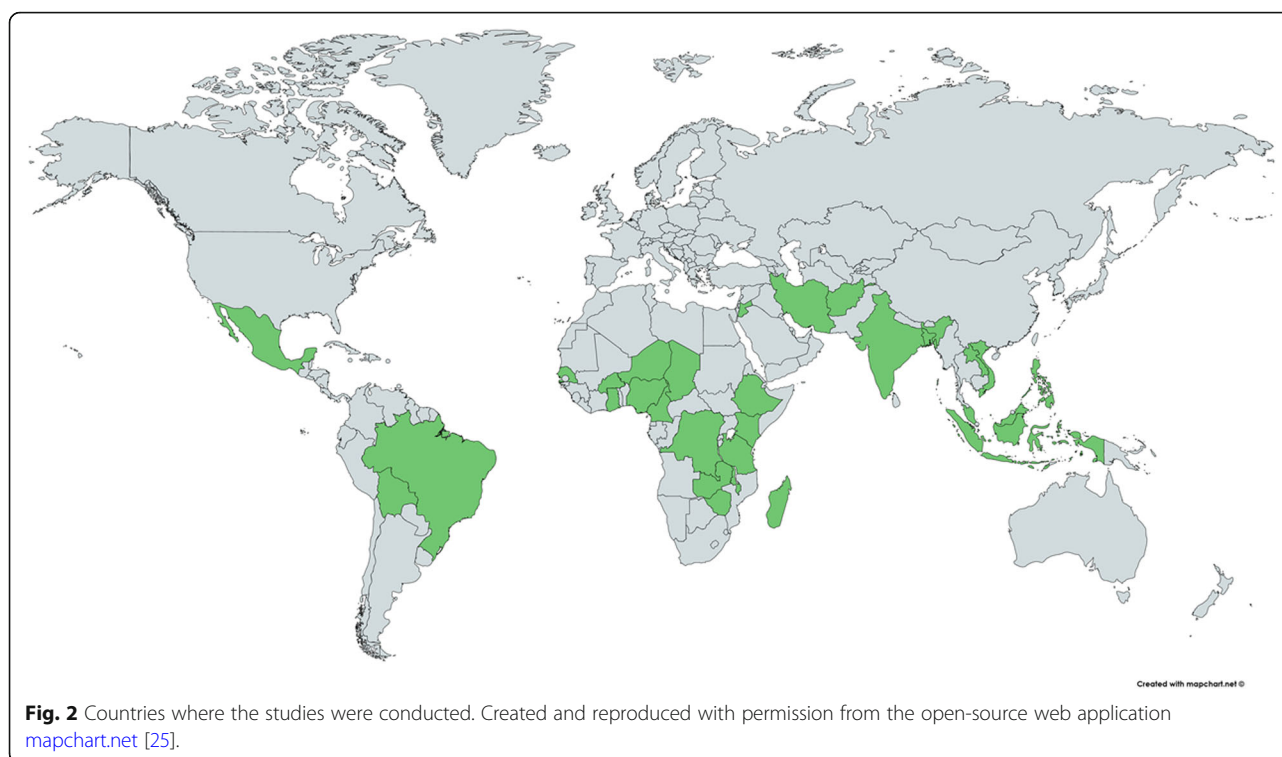

Three studies reported an association between a short birth interval and no contraception use, while one publication reported the contrary. The latter study used data from Demographic and Health Surveys from nine sub-Saharan African countries between 1991 and 2001.

Five studies reported more short birth interval with less education, but one study reported more short birth interval with more education. Two studies reported an

association between short birth interval and less parity, while one study reported the contrary.

Two studies reported more short birth interval with lower income, while one study reported the contrary. Similarly, a study reported an association between short birth interval and fewer assets. One study reported more short birth interval for people living in rural areas compared with people living in urban settings.

Three studies reported an association between short birth interval and an adverse outcome of a previous pregnancy, but one study found longer birth interval after a previous abortion. One study found more short

birth interval after a singleton birth compared with after a multiple birth. One study found more short birth interval when the place of delivery of the index child was not a health facility. Two studies found more short birth interval when the sex of the previous child was female.

An experimental study found more short birth interval with maternal and newborn health care only, compared with integrated post-partum family planning and maternal and newborn health care. Four studies reported other factors associated with birth intervals such as marital status of the mother, occupation of husband, place of residence, year, and religion (Table 2).

After adjusting for confounders, six studies reported non-significant associations between different factors and short birth interval. The studies explored age of the mother at the moment of the study (four publications), education of the mother (three), contraception method, marital status of the mother, occupation of the mother, and place of residence (two publications each category). Other factors examined included contraception use, age at last delivery, age of the woman's mother at first pregnancy, type of breastfeeding, occupation of the husband, parity of the mother, delivery place of the previous pregnancy, planned previous pregnancy, and income level (one publication each category).

Studies reporting HR

Interpretation of time-to-event data is challenging since the nature of association may change over time. For example, more education can lead to longer birth intervals

in the first two births, but it may have the opposite effect for subsequent births. We have summarized the authors' overall conclusions for each study (Additional file 4).

Among the 16 studies reporting HR, researchers most frequently reported on factors such as education (eight studies), previous pregnancy outcome (seven), age of the mother (six), breastfeeding (four), and socioeconomic level (three). All the studies reported mixed results for all factors except for breastfeeding, for which four studies found more short birth interval with shorter breastfeeding in all the pregnancies.

Three studies reported shorter birth intervals with a younger age of the mother, while one study reported the contrary. Two studies that looked at age at marriage and birth interval reported mixed results, and one study found shorter birth intervals with younger age at first birth.

Four studies found shorter birth intervals with lower education of the mother, while three studies found the contrary, and two other studies found mixed results. Five studies found shorter birth intervals with adverse outcomes in any previous pregnancy, while one study found the opposite. Two studies found mixed results.

One study reported a shorter birth interval with roundworm (*Ascaris lumbricoides*) infection but extended inter-birth intervals with hookworm infection. Another study found longer birth intervals among women with HIV infection.

One study reported shorter birth intervals among married couples, while another study found shorter birth

Table 1 Characteristics of included studies

First author and year of publication	Country	Sample size	Unit of analysis	Age range/mean (years)	Aim of the study
Studies reporting OR/RR					
Abdullah 2018 ^a	Bangladesh	4504	Women	15 to 35+	"examines the feasibility of integrating a post-partum family planning intervention package within a community-based maternal and newborn health intervention package, and evaluates the impact of integration on reduction of rates of short birth intervals and preterm births."
Hailu 2016 ^b	Ethiopia	636	Women	Mean 31 (SD \pm 5.16)	"assess determinants of interbirth interval among child-bearing age women who have at least two consecutive live births in Arba Minch Zuria Woreda, SNNP, Ethiopia, 2014."
Chirwa 2014 ^c	Democratic Republic of Congo	7172	Women	15 to 49	"investigate the proportion of short birth intervals at the provincial level among young women in the DRC."

intervals with shorter duration of the marriage. Regarding socioeconomic level, a study found shorter birth intervals with lower income, another study found a shorter birth interval with rural residence, and a third study found mixed results (place of residence).

Six studies found shorter birth intervals with less parity, postpartum amenorrhea less than 6 months, when the previous child is a girl, not using modern contraception, when religion is Catholic, farmer as a profession, and less female decision-making autonomy. An intervention study found longer birth intervals with early short-term infant supplementation. A study found mixed results on birth interval for media exposure and employment status of the women.

Qualitative and mixed-methods studies

We identified nine themes among the findings of the qualitative studies. The leading theme was local concepts and practices (14 codes), followed by modernization (eight), communication (six), religion (four), breastfeeding, health concerns, knowledge and attitudes, miscellaneous (two codes each theme), and autonomy (one).

According to the participants of the studies, the observance of local traditions prevents short birth interval. Examples include *agbon*, described as a “female body odor after parturition” that is to be respected before restarting sexual activity; *apa*, which requires avoiding a conflictive situation between children if spaced too closely; and *ratat*, a traditional period of abstinence. Researchers also reported the influence of local medicine people (hilots, marabu), traditional medicine, use of amulets, talismans, and cords, coitus interruptus, polygamy, and social taboo on the length of birth interval.

Modernization was another concept reported by researchers. The participants of the studies explained that modernization introduces social changes influencing birth intervals such as loss of culture and traditions, men staying at home more often, availability of health services, education, and food, and changes in religion and beliefs. Availability of health services and infrastructure, and family planning education prolong birth interval, while the rest of the factors related to modernization promote short birth interval.

According to the participants of the qualitative studies, birth interval was also affected by communication between couples and families, the influence of local media and the society, and observation of other parents. Concerns for maternal and child health were mentioned as tending to increase birth interval, as was knowledge about contraception methods.

Some participants mentioned that breastfeeding prolongs birth interval, while other participants questioned its effectiveness as a means of preventing an early next pregnancy. Finally, Catholicism and Hinduism were considered to

shorten birth spacing, and women’s autonomy, drought, and war were also mentioned to affect the timing of births. Table 3 gives a list of themes, codes, and quotations.

Meta-analysis

We decided not to conduct a meta-analysis. The included quantitative studies were very heterogeneous in their definitions of exposures and outcomes, and most used a cross-sectional design with variable approaches to dealing with potential confounders.

Quality assessment

The quality of most documents ranked as medium (23 documents), followed by high (16 documents), and low (four documents). For information about the quality assessment please see Additional file 5.

Discussion

Our systematic review shows two factors consistently associated with short birth interval: shorter breastfeeding and a female previous child. Younger age of the mother, less education of the mother, a negative outcome of the previous pregnancy, and lower socioeconomic status were often associated with short birth interval, although some studies reported the opposite. The quantitative studies examined a limited number of factors that could be easily included in a questionnaire.

Quantitative findings

A contraceptive effect of breastfeeding has long been recognised to prolong birth interval. Breastfeeding causes lactational amenorrhea because the suckling stimulus downregulates hypothalamic gonadotropin-releasing hormone secretion and the production of luteinizing hormone [26].

In 1988, an international group of scientists met at Bellagio, Italy [27], with the support of the WHO, the Rockefeller Foundation, and Family Health International. The group discussed the role of breastfeeding in family planning and concluded that lactational amenorrhoea can be used as a method of contraception. Institutions have followed this advice for decades. The 2017 UK Faculty of Sexual & Reproductive Healthcare Guideline on Contraception After Pregnancy [28] stated that “women may be advised that, if they are less than 6 months postpartum, amenorrhoeic and fully breastfeeding, the lactational amenorrhoea method (LAM) is a highly effective method of contraception.”p21.

Despite current efforts to promote breastfeeding worldwide, early weaning is still common and few children receive exclusive breastfeeding by the age of 6 months [29]. A recent review conducted by Bellù [30] found that breastfeeding support is complex and involves individual, structural, and environmental factors.

Table 3 Factors associated with birth spacing from qualitative studies

Author and year of publication	Theme	Factor	Quotation	Page
Social & Rural Research Institute 2006	Autonomy	Lack of decision-making power	"Lack of decision-making powers among the women due to the patriarchal structure of the family that gives the man the reins of power."	4
Millard 1984	Breastfeeding	Breastfeeding does not work	"When the issue of lactation contraception is raised with village women, they deny its effectiveness, confidently and laughingly pointing to their own repeated experiences of returning to pregnancy while breastfeeding. They volunteered information no about the return of menses in relation to the probability of conception. Of the women queried about lactation contraception, only one woman in Amanalco stated that she thought breastfeeding probably did reduce the chance of a rapidly ensuing pregnancy."	9
Adeokun 1982		Breastfeeding works	"I do not worry my mind about pregnancy, we keep on having sex and as long as she keeps on breast-feeding nothing can happen. Once she has stopped and her period has returned, then we know it is time for her to become pregnant."	10
De Vera 2007	Communication	Couple	"The subcategory, lack of communication, was identified as one of the reasons that couples did not space births."	242
Adeokun 1982		Family	"The openness of Yoruba families encourages kin and in-laws to influence a couple's decisions about child rearing and the timing of the next child."	12
De Vera 2007			"Family and friends influenced couples' decisions about birth spacing. Some participants received advice on birth spacing from relatives and friends."	244
Social & Rural Research Institute 2004			"Familial and cultural factors that determine the extent of support lent by the family (or the lack of it) to the woman. Given the nature of the Indian society, the influence of the peers and the community is critical."	4
De Vera 2007		Media	"The popular media (print and broadcast media) may exert influence on couples' decisions about spacing births in some communities."	244
		Observation	"Whereas others observed that their relatives went through hard lives because of too closely spaced pregnancies."	244
Social & Rural Research Institute 2009		Social	"Fear of social disapproval [is a barrier to adoption of spacing]."	4
Kiluvia 1991		Women's responsibility	"Communication between spouses' partners on child spacing was not necessary. Reasons varied with age and gender.[...]. Married men also frequently saw no reason to talk to their wives, because they felt the number and timing of births was solely their responsibility."	7
Chad Ministry of Public Health 1992			"While Chadians of both sexes agreed that ideally both husband and wife should decide to use child spacing together, there was consensus that it was ultimately a woman's responsibility to ensure that children were spaced."	8
Van de Walle 1986	Health concerns	Child health concerns	"If you have a child in your arms and you become pregnant again, it is not good. The child is tired and you, who are with a belly, are tired also... the child in your womb suffers too. Everyone will suffer, because you must feed the other one in addition to this one. The one in your womb will be tired too. You know that if there is no one to take care of the oldest one you will be obliged to carry it on top of your pregnancy."	17
		Maternal health concerns	"Question. When do you want the next child? Answer: Even if it takes 3 or 4 years, I will be happy. Question: Why do you want to wait? Answer: Because I am old and a lot of blood poured out of my body during my deliveries. Can the same blood flow back into my body so rapidly?"	16
Social & Rural Research Institute 2003	Knowledge and attitudes	Attitudes of the women	"Personal factors driven primarily by the attitude of the woman to self and spacing."	4
		Knowledge	"Ignorance of methods available and negligent attitude towards the concept of spacing per se that is catapulted either by the negative word of mouth or bad personal experiences."	
Dehne 2003	Local concepts and practices	Abstinence norms	"Women adhering to Gurmance traditional religion reported either 24 or 36 months' taboos, while Muslims reported much shorter norms. Most Hamallists (and the few Wahabiya) women reported a 40-day norm as prescribed in the Koran, while many 'moderate' Muslims reported intermediate norms of 2–5 months."	60
Van de Walle 1986		Afraid of being mocked	"As to the women, they crave for a child after 2 years, they are afraid of being mocked because they are finished with childbearing."	28
Adeokun 1981		Agbon (female body odor)	"The condition called agbon or female body odor after parturition. Once the period of agbon is over, sexual activity is commenced. The interbirth interval is thus a function of the length of agbon, the length of postpartum amenorrhoea, and the practice of pregnancy prevention after agbon has ended."	14
Dehne 2003		Amulets, talismans, and cords	"The use of amulets, talismans, and cords [...] for instance in cases where women felt unprotected against an early pregnancy or guilty after having resumed sexual relations shortly after a preceding birth."	60
Adeokun 1981		Apa (conflict between children)	"The other Ikale strategy starts from the notion of apa, that is, the principle that if a surviving child is less than 1 year old and another pregnancy occurs, a conflict situation arises between the survival of the nursing child and the survival of the foetus. In order to avoid the conflict, the marital sexual relationship of the parents may be organized in such a way as to prevent the	14

Author and year of publication	Theme	Factor	Quotation	Page
Millard 1984		Coitus interruptus	undesirable pregnancy." "Conjugal disruption is more frequent in Tepetlaoxtoc and may be a contributing factor; possibly conscious efforts are more often made to birth extend intervals through coitus interruptus."	7
De Vera 2007		Hilots (abortion for birth spacing)	"Most participants said that abortion was common and a de facto method for spacing births. Because abortion is illegal in the Philippines, women sought hilots (unlicensed lay abortionists, midwives, and masseuses) to perform an abortion."	243
Kiluvia 1991		Honoured tradition	"We were strongly advised by our parents to take care of the baby for 2 years, then from here you can start thinking about having another baby. We were strictly warned of having too closely spaced children."	17
Chad Ministry of Public Health 1992			"Child spacing was seen as a tradition that protected children's and women's health."	ii
Lovel 1983		Local knowledge	"These results show that in a traditional society the health benefits of birth spacing to mother and child are clearly well-known."	162
Dehne 2003		Marabu	"When this was becoming difficult, because my husband no longer agreed to abstain, I went to see a Marabu who gave me an amulet."	60
Dean 1994		Polygamy	"The influence of the post-partum abstinence period on birth interval and fertility is important. As outlined, men traditionally visit several wives, living far apart, each for a few months at a time, and this helps to sustain the post-partum abstinence period."	1581
		Ratat (traditional abstinence)	"Results of this study found that there was a traditional form of contraception throughout the district, called ratat or rotow in most areas."	
Lovel 1983		Social taboo	"More than a quarter of the families (rural 26%, semiurban 30%) said that in their parents' generation people were ashamed of having children too close together because it was not accepted in the culture."	161
Van de Walle 1986			"Ah, two years [between children] is good. Certain women don't reach 2 years. Certain women whose child is not yet walking become pregnant. I cannot understand that... If you have a child in your arms, and become pregnant, don't you know that you are humiliated [loose face]?"	16
Kiluvia 1991			"Many of the older women felt that engaging in sexual intercourse while the mother is still breastfeeding is taboo."	18
Adeokun 1982		Traditional medicine	"The other half depends on the use of herbs and traditional devices in the prevention of pregnancy."	11
De Vera 2007			"Five of the seven women admitted using some medicinal herbs and roots to stop pregnancy or stimulate menstruation."	243
Kiluvia 1991			"Young men also knew few details of how traditional methods work, but they had heard about the traditional use of herbs and abstinence for birth spacing. [...] Among the most frequently mentioned methods were abstinence; "pigi" and "fungo," in which a traditional healer ties twigs from a special tree or a "medicated" piece of cloth around a woman's waist; herbal potions; and douching."	9
De Vera 2007	Modernization	Family planning education	"The health center teaches the use of the modern methods of contraception such as pills and IUD."	244
Social & Rural Research Institute 2005		Institutional infrastructure	"Institutional infrastructure provided to the populace has also played a decisive role in adoption of spacing methods."	4
Dehne 2003		Loss of culture	"Many changes have occurred in local customs. Today, the women do not abstain for as long as we used to do."	61
Dean 1994			"Other major factors thought to cause a decrease in child spacing were the loss of tradition generally, the loss of ratat and the loss of the post-partum abstinence period."	1581
		Men stay at home more	"With the general degeneration of the traditional society the "men staying at home more" is likely to result in the decrease of the post-partum abstinence period."	Fig. 8, page 1582
		More food	"When asked specifically what women thought had caused the decrease in birth interval they gave several reasons over and above those relating to traditions, the most important of which was increase in food availability."	1578
		More health services	"More health services [cause a decrease in child spacing]."	1579
		More hygiene	"More hygiene [causes a decrease in child spacing]."	Fig. 4, page 1579
Dehne 2003		Religion	"In former times, couples waited for one to two year(s) before resuming sexual contacts. Now the waiting period is 2 months or even 40 days.[...] These changes have all occurred because of the increasing influence of religion. Many people listen to the Marabu now and attend Koranic schools."	60 & 61
Dean 1994	Other	Less drought	"Less drought [causes a decrease in child spacing]."	Fig. 4, page 1579
		Less war	"Less war [causes a decrease in child spacing]."

De Vera 2007	Religion	Catholicism	"However, one mother stated that because of the religious saying, "children are gifts from God," couples end up having many children because they do not have a choice but to accept them."	243
Adeokun 1982		God's will	"Chance or God's will in the avoidance of an inconvenient pregnancy."	10
Social & Rural Research Institute 2008		Hinduism	"Religious prohibitions dictated by certain scriptures have led to believers not subscribing to spacing."	4
Chad Ministry of Public Health 1992		Religion	"Religion was also used as a reason by some men, in both Sarh and N'Djamena, for not practicing birth spacing because children were a gift from God."	v

A better understanding of the factors associated with short breastfeeding is needed. Our review did not aim to identify factors associated with a shorter duration of breastfeeding; this issue should be addressed in future research.

Preference for a son is widespread in North Africa, East and South Asia, and the Middle East [31]. In these regions, people reportedly prefer sons because they earn more, they perpetuate the family line, and they are recipients of the family inheritance [32]. One of the included studies [8] commented that Ethiopian families see a son as an economic asset.

Studies reported mixed results for associations with a negative outcome of the previous pregnancy, age of the mother, education, and socioeconomic level, although with a preponderance of findings in one direction in each case. Researchers conducting the studies in this review often reported an association between adverse outcome of the previous pregnancy, including abortion, pregnancy loss, and multiple birth, and short birth interval. The author of one of the included studies [15] suggested that an adverse outcome might influence women to hurry into the next pregnancy without fully recovering from the last pregnancy. Early researchers on child mortality and fertility described this phenomenon as replacement: "replacement would be the response to experienced mortality [...] If children die very young and the mother can have another child, the same life cycle can be approximated by replacement." [33] p164

Most studies found more short birth interval with a younger age of the mother. Younger women are generally more fertile and more sexually active; very young women are likely to be economically disadvantaged, and may have less access to and use of modern contraception, which can explain this association [34–36], though the way this plays out will depend on the local context of each region. Older women are likely to have reached their desired family size and are less fertile, and therefore prone to prolong birth intervals [37, 38].

Most studies reported that less-educated women have more short birth interval. Hailu [8] explains that educated women have a better-informed decision-making process, have greater autonomy, and use higher quality

health care services. One study, however, reported opposite results. Highly educated women tend to delay their first pregnancy [39] and RamaRao et al. [37] hypothesized that educated women may want to compress motherhood into fewer years and therefore are likely to have shorter birth intervals.

Most studies in our review found more short birth interval among economically underprivileged women. Hailu [8] suggests that wealthier women have better access to health care information, services, and supplies and therefore, can apply modern contraception to prolong birth intervals.

Similarly, most studies reported expected associations between longer birth intervals with modern contraception use. One cross-sectional study based on DHS surveys reported opposite results [40] and the authors suggested this association between short birth interval and modern contraceptive use could have been due to temporality bias, such that women who had experienced an unintended short birth interval were then preferentially motivated to use modern contraception.

Some of the studies in this review failed to find significant associations between age of the mother, education, contraception method, marital status, occupation, and place of residence, and short birth interval. Together with the fact that some studies showed associations in the opposite direction to the prevalent findings, this suggests that associations with factors such as age and education of the mother are not universal and may be highly dependent on the particular context.

Qualitative findings

Qualitative studies explored the perceived effects of local concepts and practices not considered in quantitative studies. For example, in Burkina Faso [41] and Kenya [42], studies reported loss of traditional concepts and practices that prolong birth intervals, as a result of modernization. These qualitative findings could help to explain some associations in quantitative studies. For example, it is possible the associations between higher education and higher socioeconomic level and short birth interval could be partly explained by loss of traditions, as

more privileged women may report higher levels of acculturation [43].

Qualitative studies considered other factors that were not examined in quantitative studies. Participants in qualitative studies mentioned that communication between couples and families, the influence of local media and the society, and observation of other parents could influence birth intervals. None of the included quantitative studies attempted to explore associations between these factors and birth interval.

Quantitative studies reported a consistent association between longer breastfeeding and longer birth interval. However, participants in one qualitative study questioned the effectiveness of breastfeeding as a means to prolong birth interval, presumably based on their own experiences [44]. The WHO cautions that breastfeeding as the sole method of contraception does not fully protect against new pregnancies; 5–10% of women with lactation amenorrhea nevertheless become pregnant [45].

Strengths and limitations

Strengths of our study include a broad search strategy guided by a librarian, inclusion of five languages, no year limit, and inclusion of quantitative, qualitative and mixed-methods research, and grey literature.

We chose not to conduct a meta-analysis due to considerable heterogeneity of study design, study quality, population characteristics, and outcome and exposure definitions. We noted the concerns of Egger and co-authors [46] that (i) residual confounding and selection bias are common in observational studies; (ii) meta-analyses of observational data may yield precise but spurious results; (iii) quantitative synthesis should not be a prominent component of systematic reviews of observational studies. Although commonly performed, meta-analysis of observational studies has been criticized and some authors have suggested that this practice should be abandoned [47].

As with all systematic reviews, our results and conclusions are limited by the quality of the original studies. Almost all the included quantitative studies were observational, with concerns about residual confounding even after multivariate analyses [46], and temporality [48] bias, not knowing if the exposure preceded the outcome.

The variability of the definition of short birth interval (24, 33, and 36 months) limits the conclusions of our study. The current WHO recommendation of an optimal birth interval [2] is based on a large body of observational studies published before 2006, most of them coming from low- and middle-income countries. In other settings such as developed countries, a birth interval between 24 to 33 months may not be considered short [49].

Conclusions

We found two factors consistently associated with short birth interval: shorter breastfeeding duration and a female previous child. Promotion of breastfeeding could help to reduce short birth interval, and has many other benefits [50]. Addressing the preference for a male child is a complex and longer-term challenge.

The quantitative and qualitative studies yielded different and complementary findings. This highlights the potential value of mixed-methods research. Quantitative researchers should look for ways to investigate factors such as local knowledge and practices, modernization, and communication. Future research should use longitudinal and experimental designs, aim for consistency in outcome and exposure definitions, and include Latin American countries.

Publisher's Note

Springer Nature remains neutral with regard to jurisdictional claims in published maps and institutional affiliations.

Ready to submit your research? Choose BMC and benefit from:

- fast, convenient online submission
- thorough peer review by experienced researchers in your field
- rapid publication on acceptance
- support for research data, including large and complex data types
- gold Open Access which fosters wider collaboration and increased citations
- maximum visibility for your research: over 100M website views per year

At BMC, research is always in progress.
